# LSMcli Restart

## Description

This command restarts Security Gateway services on the selected gateway.

### Notes:

- The `CPRID` services must run on the selected gateway. See "[cprid](#)" on [page 186](#).
- This command supports Security Gateways, SmartLSM Security Gateways, and SmartLSM Cluster Members.

## Syntax

```
LSMcli [-d] <Mgmt Server> <Username> <Password> Restart
{<RoboName> | <GatewayName>}
```

## Parameters

| Parameter                             | Description                                                                       |
|---------------------------------------|-----------------------------------------------------------------------------------|
| <code>&lt;Mgmt Server&gt;</code>      | Name or IP address of the Security Management Server or Domain Management Server. |
| <code>&lt;Username&gt;</code>         | User name of standard Check Point authentication method.                          |
| <code>&lt;Password&gt;</code>         | Password of standard Check Point authentication method.                           |
| <code>&lt;RoboName&gt;</code>         | Name of the SmartLSM Security Gateway.                                            |
| <code>&lt;GatewayName&gt;</code><br>> | Name of the standard Security Gateway.                                            |

## Example

```
LSMcli mySrvr name pass Restart MyRobo
```

# LSMcli Reboot

## Description

This command reboots the selected gateway.

### Notes:

- The `CPRID` services must run on the selected gateway. See "[cprid](#)" on [page 186](#).
- This command supports Security Gateways, SmartLSM Security Gateways, and SmartLSM Cluster Members.

## Syntax

```
LSMcli [-d] <Mgmt Server> <Username> <Password> Reboot {<RoboName>
| <GatewayName>}
```

## Parameters

| Parameter                             | Description                                                                       |
|---------------------------------------|-----------------------------------------------------------------------------------|
| <code>&lt;Mgmt Server&gt;</code>      | Name or IP address of the Security Management Server or Domain Management Server. |
| <code>&lt;Username&gt;</code>         | User name of standard Check Point authentication method.                          |
| <code>&lt;Password&gt;</code>         | Password of standard Check Point authentication method.                           |
| <code>&lt;RoboName&gt;</code>         | Name of the SmartLSM Security Gateway.                                            |
| <code>&lt;GatewayName&gt;</code><br>> | Name of the standard Security Gateway.                                            |

## Example

```
LSMcli mySrvr name pass Reboot MyRobo
```

# LSMcli Push Actions

These commands are used to push updated values, settings, and security rules to gateways.

After you create a gateway or a dynamic object in the SmartProvisioning system, you must assign (push) a security policy to it.

# LSMcli PushPolicy

## Description

This command pushes a policy to the selected gateway.

### Notes:

- The `CPRID` services must run on the selected gateway. See "[cprid](#)" on [page 186](#).
- This command supports Security Gateways, SmartLSM Security Gateways, and SmartLSM Clusters.

## Syntax

```
LSMcli [-d] <Mgmt Server> <Username> <Password> PushPolicy
{<RoboName> | <GatewayName>}
```

## Parameters

| Parameter                             | Description                                                                       |
|---------------------------------------|-----------------------------------------------------------------------------------|
| <code>&lt;Mgmt Server&gt;</code>      | Name or IP address of the Security Management Server or Domain Management Server. |
| <code>&lt;Username&gt;</code>         | User name of standard Check Point authentication method.                          |
| <code>&lt;Password&gt;</code>         | Password of standard Check Point authentication method.                           |
| <code>&lt;RoboName&gt;</code>         | Name of the SmartLSM Security Gateway, or SmartLSM Cluster.                       |
| <code>&lt;GatewayName&gt;</code><br>> | Name of the standard Security Gateway.                                            |

## Example

```
LSMcli mySrvr name pass PushPolicy MyRobo
```

# LSMcli PushDOs

## Description

This command updates a Dynamic Object's information on the SmartLSM Security Gateway or SmartLSM Cluster Member.

 **Note** - This command does not remove/release the IP address range for the deleted Dynamic Object, but only adds new ones. To overcome this difficulty, run the *"LSMcli PushPolicy" on page 934* command.

## Syntax

```
LSMcli [-d] <Mgmt Server> <Username> <Password> PushDOs <RoboName>
```

## Parameters

| Parameter     | Description                                                                       |
|---------------|-----------------------------------------------------------------------------------|
| <Mgmt Server> | Name or IP address of the Security Management Server or Domain Management Server. |
| <Username>    | User name of standard Check Point authentication method.                          |
| <Password>    | Password of standard Check Point authentication method.                           |
| <RoboName>    | Name of the SmartLSM Security Gateway or SmartLSM Cluster Member.                 |

## Example

```
LSMcli mySrvr name pass PushDOs MyRobo
```

# LSMcli GetStatus

## Description

This command fetches various statistics from the selected gateway.

**Note** - This command supports Security Gateways, SmartLSM Security Gateways, and Gateway or SmartLSM Cluster Members.

## Syntax

```
LSMcli [-d] <Mgmt Server> <Username> <Password> GetStatus
{<RoboName> | <GatewayName>}
```

## Parameters

| Parameter          | Description                                                                       |
|--------------------|-----------------------------------------------------------------------------------|
| <Mgmt Server>      | Name or IP address of the Security Management Server or Domain Management Server. |
| <Username>         | User name of standard Check Point authentication method.                          |
| <Password>         | Password of standard Check Point authentication method.                           |
| <RoboName>         | Name of the SmartLSM Security Gateway or SmartLSM Cluster Member.                 |
| <GatewayName><br>> | Name of the standard Security Gateway.                                            |

## Example

```
LSMcli mySrvr name pass GetStatus MyRobo
```

# Managing SmartLSM Clusters with LSMcli

With the `LSMcli` command, you can define SmartLSM clusters, and configure most of the options available in SmartProvisioning GUI (in the **New SmartLSM Cluster** wizard and in the **Edit** windows).

This section lists unique commands for SmartLSM Clusters.

Other commands that also apply to SmartLSM Clusters:

- [\*"LSMcli Distribute" on page 922\*](#)
- [\*"LSMcli GetInfo" on page 926\*](#)
- [\*"LSMcli GetStatus" on page 936\*](#)
- [\*"LSMcli Install" on page 919\*](#)
- [\*"LSMcli ModifyROBOManualVPNDomain" on page 903\*](#)
- [\*"LSMcli PushDOs" on page 935\*](#)
- [\*"LSMcli PushPolicy" on page 934\*](#)
- [\*"LSMcli Reboot" on page 932\*](#)
- [\*"LSMcli Reboot" on page 932\*](#)
- [\*"LSMcli ResetIke" on page 910\*](#)
- [\*"LSMcli ResetSic" on page 912\*](#)
- [\*"LSMcli Restart" on page 931\*](#)
- [\*"LSMcli ShowInfo" on page 927\*](#)
- [\*"LSMcli Start" on page 930\*](#)
- [\*"LSMcli Stop" on page 929\*](#)
- [\*"LSMcli Uninstall" on page 921\*](#)
- [\*"LSMcli Upgrade" on page 925\*](#)
- [\*"LSMcli VerifyInstall" on page 923\*](#)
- [\*"LSMcli VerifyUpgrade" on page 924\*](#)

**Note** - There is no convert action for or to SmartLSM clusters.

# LSMcli AddROBO VPN1Cluster

## Description

This command defines a new SmartLSM cluster.

You can configure all of the options available in the **New SmartLSM Cluster** wizard of the SmartProvisioning GUI.

The only exception is the configuration of Topology overrides (see ["LSMcli ModifyROBONetaccess VPN1Cluster" on page 942](#)).

## Syntax

```
LSMcli [-d] <Mgmt Server> <Username> <Password> AddROBO
VPN1Cluster <Profile> <MainIPAddress> <SuffixName> [-
S=<SubstitutedNamePart>] [-CA=<CaName> [-R=<KeyIdentifier#>] [-
KEY=<AuthorizationCode>]]
```

## Parameters

| Parameter             | Description                                                                       | SmartLSM GUI Location                                                         |
|-----------------------|-----------------------------------------------------------------------------------|-------------------------------------------------------------------------------|
| <Mgmt Server>         | Name or IP address of the Security Management Server or Domain Management Server. |                                                                               |
| <Username>            | User name of standard Check Point authentication method.                          |                                                                               |
| <Password>            | Password of standard Check Point authentication method.                           |                                                                               |
| <Profile>             | Name of cluster Profile to which to map the new cluster.                          | <b>New SmartLSM Cluster</b> wizard.                                           |
| <MainIPAddress>       | Main IP address of cluster.                                                       | <b>New SmartLSM Cluster</b> wizard.                                           |
| <SuffixName>          | A suffix to be added to cluster and member Profile names.                         | <b>New SmartLSM Cluster</b> wizard.                                           |
| <SubstitutedNamePart> | A part of the Profile name to be replaced by the suffix in the previous field.    | SmartProvisioning GUI supports adding Prefix and/or Suffix, not substitution. |

| Parameter                              | Description                                                                                             | SmartLSM GUI Location                                                          |
|----------------------------------------|---------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------|
| <code>&lt;CaName&gt;</code>            | The name of the Trusted CA object, defined in SmartConsole, to which a VPN certificate request is sent. | Double-click the SmartLSM cluster object > <b>Edit</b> window > <b>VPN</b> tab |
| <code>&lt;KeyIdentifier#&gt;</code>    | Number to identify the specific certificate, once generated.                                            | Double-click the SmartLSM cluster object > <b>Edit</b> window > <b>VPN</b> tab |
| <code>&lt;AuthorizationCode&gt;</code> | Authorization Key to be sent to CA to enable certificate retrieval.                                     | Double-click the SmartLSM cluster object > <b>Edit</b> window > <b>VPN</b> tab |

# LSMcli ModifyROBO VPN1Cluster

## Description

You can change a SmartLSM cluster main IP address.

You can resolve a dynamic object for a SmartLSM cluster.

## Syntax for changing the Main IP Address

You can change a SmartLSM cluster main IP address in the SmartProvisioning GUI (double-click the SmartLSM cluster object > **Edit** window > **Cluster** tab), or with this command:

```
LSMcli [-d] <Mgmt Server> <Username> <Password> ModifyROBO
VPN1Cluster <ROBOClusterName> -I=<MainIPAddress>
```

## Syntax for resolving a Dynamic Object

You can resolve a dynamic object for a SmartLSM cluster in the SmartProvisioning GUI (double-click the SmartLSM cluster object > **Edit** window > **Dynamic Objects** tab), or with this command:

```
LSMcli [-d] <Mgmt Server> <Username> <Password> ModifyROBO
VPN1Cluster <ROBOClusterName> -D:<DO Name>={<IP> | <IP1-IP2>}
```

## Parameters

| Parameter            | Description                                                                       |
|----------------------|-----------------------------------------------------------------------------------|
| <Mgmt Server>        | Name or IP address of the Security Management Server or Domain Management Server. |
| <Username>           | User name of standard Check Point authentication method.                          |
| <Password>           | Password of standard Check Point authentication method.                           |
| <Profile>            | Name of cluster Profile to which to map the new cluster.                          |
| <MainIPAddress><br>> | Main IP address of cluster.                                                       |
| <DO Name>            | Name of the Dynamic Object.                                                       |
| <IP>                 | Single IP address.                                                                |
| <IP1-IP2>            | Range of IP addresses.                                                            |

# LSMcli ModifyROBOTopology VPN1Cluster

## Description

You can set the VPN domain of a SmartLSM cluster in the SmartProvisioning GUI (double-click the SmartLSM cluster object > **Edit** window > **Topology** tab), or with this command.

**Note** - When the VPN domain is set to Manual, the IP address ranges are those set in the SmartProvisioning GUI, or with the ["LSMcli ModifyROBOManualVPNDomain" on page 903](#) command.

## Syntax

```
LSMcli [-d] <Mgmt Server> <Username> <Password> ModifyROBOTopology
VPN1Cluster <RoboClusterName> -VPNDomain={not_defined | external_
ip_only | topology | manual}
```

## Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <Mgmt Server>     | Name or IP address of the Security Management Server or Domain Management Server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <Username>        | User name of standard Check Point authentication method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

VPN domain is defined according to the configuration made with the <a href="#">"LSMcli ModifyROBOManualVPNDomain" on page 903</a> command.</li> </ul> |

# LSMcli ModifyROBONetaccess VPN1Cluster

## Description

For the actual SmartLSM cluster, you can override the profile topology definitions of a cluster (virtual) interface in the SmartProvisioning GUI (double-click the SmartLSM cluster object > **Edit window > Topology** tab), or with this command.

## Syntax

```
LSMcli [-d] <Mgmt Server> <Username> <Password>
ModifyROBONetaccess VPN1Cluster <ClusterName> <InterfaceName> -
Mode={by_profile|override} [-TopologyType={external|internal}] [-
DMZAccess={true|false}] [-InternalIP={not_defined|this|specific}
[-AllowedGroup=<GroupName>]] [-AntiSpoof={true|false} [-
AllowedGroup=<GroupName>] [-SpoofTrack={none|log|alert}]]
```

## Parameters

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                 |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <Mgmt Server>        | Name or IP address of the Security Management Server or Domain Management Server.                                                                                                                                                                                                                                                                           |

| -AntiSpoof    | <p>Specifies whether to perform Anti-Spoofing:</p> <ul style="list-style-type: none"> <li>true - Perform Anti-Spoofing based on interface topology. In this case, optionally use the "-AllowedGroup" and "-SpoofTrack".</li> <li>false - Do not perform Anti-Spoofing. If the interface is internal, and the IP addresses behind the interface are not defined, Anti-Spoofing is not possible.</li> </ul>         |
| -AllowedGroup | <p>If Anti-Spoofing is performed, specifies the Network Group object, from which packets are not checked.</p> <ul style="list-style-type: none"> <li>If "-TopologyType=external", this parameter defines a group, from which packets are not checked if Anti-Spoofing is performed</li> <li>If "-TopologyType=internal", this parameter explicitly defines the networks behind the internal interface.</li> </ul> |
| -SpoofTrack   | <p>If Anti-Spoofing is performed, specifies the tracking action when spoofing is detected:</p> <ul style="list-style-type: none"> <li>none - No action</li> <li>log - Generate a log</li> <li>alert - Show an alert popup</li> </ul>                                                                                                                                                                              |

# LSMcli AddClusterSubnetOverride VPN1Cluster

## Description

These settings in SmartLSM cluster objects get default values from their Profiles:

- Names of cluster member interfaces
- IP addresses of cluster member interfaces

These default values can (and in the case of IP addresses, usually must) be overridden for the individual SmartLSM cluster.

You can edit the interface properties in the SmartProvisioning GUI (in the **New SmartLSM Cluster** wizard, or double-click the SmartLSM cluster object > **Edit** window > **Topology** tab), or with this command.

### Notes:

- If there is a set override value, and you want to change it, then use only the ["LSMcli ModifyClusterSubnetOverride VPN1Cluster" on page 946](#) command.
- If the override value you want to set is **not** defined (except at the **Profile** level), because it was never defined or because it was deleted, then use only this "AddClusterSubnetOverride" command.
- To cancel a value and return to the value set by the **Profile**, use the ["LSMcli DeleteClusterSubnetOverride VPN1Cluster" on page 948](#) command.
- To define overrides for a private (monitored or non-monitored) interface, use one of these commands:
  - ["LSMcli AddPrivateSubnetOverride VPN1ClusterMember" on page 950](#)
  - ["LSMcli ModifyPrivateSubnetOverride VPN1ClusterMember" on page 952](#)
  - ["LSMcli DeletePrivateSubnetOverride VPN1ClusterMember" on page 954](#)

## Syntax

```
LSMcli [-d] <Mgmt Server> <Username> <Password>
AddClusterSubnetOverride VPN1Cluster <ROBOClusterName>
<InterfaceName> [-IName=<MembersInterfaceName>] [-
MNet=<MembersNetAddress>] [-CIP=<ClusterIPAddress> -
CNetMask=<ClusterNetMask>]
```

You must define at least one of these parameters:

- "-IName"
- "-MNet"
- "-CIP" *and* "-CNetMask"

## Parameters

| Parameter                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;Mgmt Server&gt;</code>     | Name or IP address of the Security Management Server or Domain Management Server.                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>&lt;Username&gt;</code>        | User name of standard Check Point authentication method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>&lt;Password&gt;</code>        | Password of standard Check Point authentication method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>&lt;ROBOClusterName&gt;</code> | Name of the SmartLSM cluster.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>&lt;InterfaceName&gt;</code>   | <p>Name of cluster (virtual) interface, as defined in the <b>Profile</b> topology.</p> <p>Use the name of the cluster interface even if you set values for cluster members' interfaces.</p> <p>If the cluster interface's <b>Network Objective</b> (as defined in the <b>Profile</b> topology) is <b>Sync only</b> (and not <b>Cluster+Sync</b>), there is no cluster interface, only cluster member interface.</p> <p>In this case use the <b>Network Objective</b> (for example, <b>1st Sync</b>) for this parameter.</p> |
| <code>-IName</code>                  | <p>New name of the interface for cluster members.</p> <p>The name must match the name defined in the operating system of the cluster members.</p>                                                                                                                                                                                                                                                                                                                                                                           |
| <code>-MNet</code>                   | <p>New network address for cluster members.</p> <p>This address, together with the host parts defined in the <b>Profile</b>, produces complete IP addresses.</p>                                                                                                                                                                                                                                                                                                                                                            |
| <code>-CIP</code>                    | New IP address for the cluster (virtual) interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>-CNetMask</code>               | Net mask for the cluster (virtual) interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

# LSMcli ModifyClusterSubnetOverride VPN1Cluster

## Description

These settings in SmartLSM cluster objects get default values from their Profiles:

- Names of cluster member interfaces
- IP addresses of cluster member interfaces

These default values can (and in the case of IP addresses, usually must) be overridden for the individual SmartLSM cluster.

You can edit the interface properties in the SmartProvisioning GUI (in the **New SmartLSM Cluster** wizard, or double-click the SmartLSM cluster object > **Edit** window > **Topology** tab), or with this command.

### Notes:

- If there is a set override value, and you want to change it, then use only this `"ModifyClusterSubnetOverride"` command.
- If the override value you want to set is **not** defined (except at the **Profile** level), because it was never defined or because it was deleted, then use only the ["LSMcli AddClusterSubnetOverride VPN1Cluster" on page 944](#) command.
- To cancel a value and return to the value set by the **Profile**, use the ["LSMcli DeleteClusterSubnetOverride VPN1Cluster" on page 948](#) command.
- To define overrides for a private (monitored or non-monitored) interface, use one of these commands:
  - ["LSMcli AddPrivateSubnetOverride VPN1ClusterMember" on page 950](#)
  - ["LSMcli ModifyPrivateSubnetOverride VPN1ClusterMember" on page 952](#)
  - ["LSMcli DeletePrivateSubnetOverride VPN1ClusterMember" on page 954](#)

## Syntax

```
LSMcli [-d] <Mgmt Server> <Username> <Password>
ModifyClusterSubnetOverride VPN1Cluster <ROBOClusterName>
<InterfaceName> [-IName=<MembersInterfaceName>] [-
MNet=<MembersNetAddress>] [-CIP=<ClusterIPAddress> -
CNetMask=<ClusterNetMask>]
```

You must define at least one of these parameters:

- `"-IName"`
- `"-MNet"`
- `"-CIP" and "-CNetMask"`

## Parameters

| Parameter                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;Mgmt Server&gt;</code>     | Name or IP address of the Security Management Server or Domain Management Server.                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>&lt;Username&gt;</code>        | User name of standard Check Point authentication method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>&lt;Password&gt;</code>        | Password of standard Check Point authentication method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>&lt;ROBOClusterName&gt;</code> | Name of the SmartLSM cluster.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>&lt;InterfaceName&gt;</code>   | <p>Name of cluster (virtual) interface, as defined in the <b>Profile</b> topology.</p> <p>Use the name of the cluster interface even if you set values for cluster members' interfaces.</p> <p>If the cluster interface's <b>Network Objective</b> (as defined in the <b>Profile</b> topology) is <b>Sync only</b> (and not <b>Cluster+Sync</b>), there is no cluster interface, only cluster member interface.</p> <p>In this case use the <b>Network Objective</b> (for example, <b>1st Sync</b>) for this parameter.</p> |
| <code>-IName</code>                  | <p>New name of the interface for cluster members.</p> <p>The name must match the name defined in the operating system of the cluster members.</p>                                                                                                                                                                                                                                                                                                                                                                           |
| <code>-MNet</code>                   | <p>New network address for cluster members.</p> <p>This address, together with the host parts defined in the <b>Profile</b>, produces complete IP addresses.</p>                                                                                                                                                                                                                                                                                                                                                            |
| <code>-CIP</code>                    | New IP address for the cluster (virtual) interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>-CNetMask</code>               | Net mask for the cluster (virtual) interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

# LSMcli DeleteClusterSubnetOverride VPN1Cluster

## Description

These settings in SmartLSM cluster objects get default values from their Profiles:

- Names of cluster member interfaces
- IP addresses of cluster member interfaces

These default values can (and in the case of IP addresses, usually must) be overridden for the individual SmartLSM cluster.

You can edit the interface properties in the SmartProvisioning GUI (in the **New SmartLSM Cluster** wizard, or double-click the SmartLSM cluster object > **Edit** window > **Topology** tab), or with this command.

### Notes:

- If there is a set override value, and you want to change it, then use only this ["LSMcli ModifyClusterSubnetOverride VPN1Cluster" on page 946](#) command.
- If the override value you want to set is **not** defined (except at the **Profile** level), because it was never defined or because it was deleted, then use only the ["LSMcli AddClusterSubnetOverride VPN1Cluster" on page 944](#) command.
- To cancel a value and return to the value set by the **Profile**, use this "DeleteClusterSubnetOverride" command.
- To define overrides for a private (monitored or non-monitored) interface, use one of these commands:
  - ["LSMcli AddPrivateSubnetOverride VPN1ClusterMember" on page 950](#)
  - ["LSMcli ModifyPrivateSubnetOverride VPN1ClusterMember" on page 952](#)
  - ["LSMcli DeletePrivateSubnetOverride VPN1ClusterMember" on page 954](#)

## Syntax

```
LSMcli [-d] <Mgmt Server> <Username> <Password>
DeleteClusterSubnetOverride VPN1Cluster <ROBOClusterName>
<InterfaceName> [-IName=<MembersInterfaceName>] [-
MNet=<MembersNetAddress>] [-CIP=<ClusterIPAddress> -
CNetMask=<ClusterNetMask>]
```

You must define at least one of these parameters:

- "-IName"
- "-MNet"
- "-CIP" *and* "-CNetMask"

## Parameters

| Parameter                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;Mgmt Server&gt;</code>     | Name or IP address of the Security Management Server or Domain Management Server.                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>&lt;Username&gt;</code>        | User name of standard Check Point authentication method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>&lt;Password&gt;</code>        | Password of standard Check Point authentication method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>&lt;ROBOClusterName&gt;</code> | Name of the SmartLSM cluster.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>&lt;InterfaceName&gt;</code>   | <p>Name of cluster (virtual) interface, as defined in the <b>Profile</b> topology.</p> <p>Use the name of the cluster interface even if you set values for cluster members' interfaces.</p> <p>If the cluster interface's <b>Network Objective</b> (as defined in the <b>Profile</b> topology) is <b>Sync only</b> (and not <b>Cluster+Sync</b>), there is no cluster interface, only cluster member interface.</p> <p>In this case use the <b>Network Objective</b> (for example, <b>1st Sync</b>) for this parameter.</p> |
| <code>-IName</code>                  | <p>New name of the interface for cluster members.</p> <p>The name must match the name defined in the operating system of the cluster members.</p>                                                                                                                                                                                                                                                                                                                                                                           |
| <code>-MNet</code>                   | <p>New network address for cluster members.</p> <p>This address, together with the host parts defined in the <b>Profile</b>, produces complete IP addresses.</p>                                                                                                                                                                                                                                                                                                                                                            |
| <code>-CIP</code>                    | New IP address for the cluster (virtual) interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>-CNetMask</code>               | Net mask for the cluster (virtual) interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

# LSMcli AddPrivateSubnetOverride VPN1ClusterMember

## Description

These settings in SmartLSM cluster objects get default values from their Profiles:

- Names of cluster member monitored interfaces or non-monitored interfaces
- IP addresses of cluster member monitored interfaces or non-monitored interfaces

These default values can (and in the case of IP addresses, usually must) be overridden for the individual SmartLSM cluster.

You can edit the interface properties in the SmartProvisioning GUI (in the **New SmartLSM Cluster** wizard, or double-click the SmartLSM cluster object > **Edit** window > **Topology** tab), or with this command.

### Notes:

- If there is a set override value, and you want to change it, then use only the ["LSMcli ModifyPrivateSubnetOverride VPN1ClusterMember" on page 952](#) command.
- If the override value you want to set is **not** defined (except at the **Profile** level), because it was never defined or because it was deleted, then use only this "AddPrivateSubnetOverride" command.
- To cancel a value and return to the value set by the **Profile**, use the ["LSMcli DeletePrivateSubnetOverride VPN1ClusterMember" on page 954](#) command.
- To define overrides for a cluster interface, use one of these commands:
  - ["LSMcli AddClusterSubnetOverride VPN1Cluster" on page 944](#)
  - ["LSMcli ModifyClusterSubnetOverride VPN1Cluster" on page 946](#)
  - ["LSMcli DeleteClusterSubnetOverride VPN1Cluster" on page 948](#)

## Syntax

```
LSMcli [-d] <Mgmt Server> <Username> <Password>
AddPrivateSubnetOverride VPN1ClusterMember <ROBOMemberName>
<InterfaceName> [-IName=<MembersInterfaceName>] [-
MNet=<MembersNetAddress>]
```

You must define at least one of these parameters:

- "-IName"
- "-MNet"

## Parameters

| Parameter                           | Description                                                                                                                                            |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;Mgmt Server&gt;</code>    | Name or IP address of the Security Management Server or Domain Management Server.                                                                      |
| <code>&lt;Username&gt;</code>       | User name of standard Check Point authentication method.                                                                                               |
| <code>&lt;Password&gt;</code>       | Password of standard Check Point authentication method.                                                                                                |
| <code>&lt;ROBOMemberName&gt;</code> | Name of the SmartLSM cluster member.                                                                                                                   |
| <code>&lt;InterfaceName&gt;</code>  | Name of cluster member private interface, as defined in the <b>Profile</b> topology.                                                                   |
| <code>-IName</code>                 | New name of the interface for cluster members.<br>The name must match the name defined in the operating system of the cluster members.                 |
| <code>-MNet</code>                  | New network address for cluster members.<br>This address, together with the host parts defined in the <b>Profile</b> , produces complete IP addresses. |

# LSMcli ModifyPrivateSubnetOverride VPN1ClusterMember

## Description

These settings in SmartLSM cluster objects get default values from their Profiles:

- Names of cluster member monitored interfaces or non-monitored interfaces
- IP addresses of cluster member monitored interfaces or non-monitored interfaces

These default values can (and in the case of IP addresses, usually must) be overridden for the individual SmartLSM cluster.

You can edit the interface properties in the SmartProvisioning GUI (in the **New SmartLSM Cluster** wizard, or double-click the SmartLSM cluster object > **Edit** window > **Topology** tab), or with this command.

### Notes:

- If there is a set override value, and you want to change it, then use only the "ModifyPrivateSubnetOverride" command.
- If the override value you want to set is **not** defined (except at the **Profile** level), because it was never defined or because it was deleted, then use only the ["LSMcli AddPrivateSubnetOverride VPN1ClusterMember" on page 950](#) command.
- To cancel a value and return to the value set by the **Profile**, use the ["LSMcli DeletePrivateSubnetOverride VPN1ClusterMember" on page 954](#) command.
- To define overrides for a cluster interface, use one of these commands:
  - ["LSMcli AddClusterSubnetOverride VPN1Cluster" on page 944](#)
  - ["LSMcli ModifyClusterSubnetOverride VPN1Cluster" on page 946](#)
  - ["LSMcli DeleteClusterSubnetOverride VPN1Cluster" on page 948](#)

## Syntax

```
LSMcli [-d] <Mgmt Server> <Username> <Password>
ModifyPrivateSubnetOverride VPN1ClusterMember <ROBOMemberName>
<InterfaceName> [-IName=<MembersInterfaceName>] [-
MNet=<MembersNetAddress>]
```

You must define at least one of these parameters:

- "-IName"
- "-MNet"

**Parameters**

| Parameter                           | Description                                                                                                                                            |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;Mgmt Server&gt;</code>    | Name or IP address of the Security Management Server or Domain Management Server.                                                                      |
| <code>&lt;Username&gt;</code>       | User name of standard Check Point authentication method.                                                                                               |
| <code>&lt;Password&gt;</code>       | Password of standard Check Point authentication method.                                                                                                |
| <code>&lt;ROBOMemberName&gt;</code> | Name of the SmartLSM cluster member.                                                                                                                   |
| <code>&lt;InterfaceName&gt;</code>  | Name of cluster member private interface, as defined in the <b>Profile</b> topology.                                                                   |
| <code>-IName</code>                 | New name of the interface for cluster members.<br>The name must match the name defined in the operating system of the cluster members.                 |
| <code>-MNet</code>                  | New network address for cluster members.<br>This address, together with the host parts defined in the <b>Profile</b> , produces complete IP addresses. |

# LSMcli DeletePrivateSubnetOverride VPN1ClusterMember

## Description

These settings in SmartLSM cluster objects get default values from their Profiles:

- Names of cluster member monitored interfaces or non-monitored interfaces
- IP addresses of cluster member monitored interfaces or non-monitored interfaces

These default values can (and in the case of IP addresses, usually must) be overridden for the individual SmartLSM cluster.

You can edit the interface properties in the SmartProvisioning GUI (in the **New SmartLSM Cluster** wizard, or double-click the SmartLSM cluster object > **Edit** window > **Topology** tab), or with this command.

### Notes:

- If there is a set override value, and you want to change it, then use only the ["LSMcli ModifyPrivateSubnetOverride VPN1ClusterMember" on page 952](#) command.
- If the override value you want to set is **not** defined (except at the **Profile** level), because it was never defined or because it was deleted, then use only the ["LSMcli AddPrivateSubnetOverride VPN1ClusterMember" on page 950](#) command.
- To cancel a value and return to the value set by the **Profile**, use the "DeletePrivateSubnetOverride" command.
- To define overrides for a cluster interface, use one of these commands:
  - ["LSMcli AddClusterSubnetOverride VPN1Cluster" on page 944](#)
  - ["LSMcli ModifyClusterSubnetOverride VPN1Cluster" on page 946](#)
  - ["LSMcli DeleteClusterSubnetOverride VPN1Cluster" on page 948](#)

## Syntax

```
LSMcli [-d] <Mgmt Server> <Username> <Password>
DeletePrivateSubnetOverride VPN1ClusterMember <ROBOMemberName>
<InterfaceName> [-IName=<MembersInterfaceName>] [-
MNet=<MembersNetAddress>]
```

You must define at least one of these parameters:

- "-IName"
- "-MNet"

## Parameters

| Parameter                           | Description                                                                                                                                            |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;Mgmt Server&gt;</code>    | Name or IP address of the Security Management Server or Domain Management Server.                                                                      |
| <code>&lt;Username&gt;</code>       | User name of standard Check Point authentication method.                                                                                               |
| <code>&lt;Password&gt;</code>       | Password of standard Check Point authentication method.                                                                                                |
| <code>&lt;ROBOMemberName&gt;</code> | Name of the SmartLSM cluster member.                                                                                                                   |
| <code>&lt;InterfaceName&gt;</code>  | Name of cluster member private interface, as defined in the <b>Profile</b> topology.                                                                   |
| <code>-IName</code>                 | New name of the interface for cluster members.<br>The name must match the name defined in the operating system of the cluster members.                 |
| <code>-MNet</code>                  | New network address for cluster members.<br>This address, together with the host parts defined in the <b>Profile</b> , produces complete IP addresses. |

# LSMcli RemoveCluster

## Description

This command:

1. Revokes all the certificates used by the SmartLSM cluster and its members.
2. Releases all the licenses.
3. Deletes the SmartLSM cluster and member objects.

## Syntax

```
LSMcli [-d] <Mgmt Server> <Username> <Password> RemoveCluster
<ROBOClusterName>
```

## Parameters

| Parameter         | Description                                                                       |
|-------------------|-----------------------------------------------------------------------------------|
| <Mgmt Server>     | Name or IP address of the Security Management Server or Domain Management Server. |
| <Username>        | User name of standard Check Point authentication method.                          |
| <Password>        | Password of standard Check Point authentication method.                           |
| <ROBOClusterName> | Name of the SmartLSM Cluster.                                                     |

# Using LSMcli Commands for Small Office Appliances

This section describes `LSMcli` commands for managing Small Office Appliances and Small Office Appliance Clusters.

# LSMcli AddROBO <Appliance\_Model>

## Description

This command adds a Small Office Appliance Gateway.

## Syntax

```
LSMcli [-d] <Mgmt Server> <Username> <Password> AddROBO
<Appliance_Model> <ROBOName> <Profile> [-O=<ActivationKey> [-
I=<IP>]] [[-CA=<CaName> [-R=<CertificateIdentifier#>] [-
KEY=<AuthorizationKey>]]
```

## Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <Mgmt Server>     | Name or IP address of the Security Management Server or Domain Management Server.                                                                                                                                                                                                                                                                                                            |
| <Username>        | User name of standard Check Point authentication method.                                                                                                                                                                                                                                                                                                                                     |
| <Password>        | Password of standard Check Point authentication method.                                                                                                                                                                                                                                                                                                                                      |
| <Appliance_Model> | Model of appliance: <ul style="list-style-type: none"> <li>■ For 1100 appliances, enter: CPSG80</li> <li>■ For 1200R appliances, enter: 1200R</li> <li>■ For 1430 or 1450 appliances, enter: 1430/1450</li> <li>■ For 1470 or 1490 appliances, enter: 1470/1490</li> <li>■ For 1530 or 1550 appliances, enter: 1530/1550</li> <li>■ For 1570 or 1590 appliances, enter: 1570/1590</li> </ul> |
| <RoboName>        | Name of a SmartLSM Security Gateway.                                                                                                                                                                                                                                                                                                                                                         |
| <Profile>         | Name of a SmartLSM Security Profile that was defined in SmartConsole.                                                                                                                                                                                                                                                                                                                        |
| <ActivationKey>   | SIC one-time password (for this action, a certificate is generated).                                                                                                                                                                                                                                                                                                                         |
| IP                | IP address of the gateway (for this action, a certificate is pushed to the gateway).                                                                                                                                                                                                                                                                                                         |

| Parameter                | Description                                                                                                                                       |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <CaName>                 | Name of the Trusted CA object (created from SmartConsole).<br>The IKE certificate request is sent to this CA. Default is Check Point Internal CA. |
| <CertificateIdentifier#> | Key identifier for third-party CA.                                                                                                                |
| <AuthorizationKey>       | Authorization Key for third-party CA.                                                                                                             |

## Examples

- To add a 1100 appliance Security Gateway:

```
LSMcli 192.168.3.26 aa aaaa AddROBO CPSG80 Paris_GW small_
office_profile
```

- To add a 1470/1490 appliance Security Gateway:

```
LSMcli 192.168.3.26 aa aaaa AddROBO 1470/1490 Paris_GW small_
office_profile
```

# LSMcli AddROBO <Appliance\_Model>Cluster

## Description

This command adds a Small Office Appliance Cluster.

## Syntax

```
LSMcli [-d] <Mgmt Server> <Username> <Password> AddROBO
<Appliance_Model>Cluster <Profile> <MainIPAddress> <SuffixName> [-
S=<SubstitutedNamePart>] [-CA=<CaName> [-R=<KeyIdentifier#>] [-
KEY=<AuthorizationCode>]]
```

## Parameters

| Parameter                | Description                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <Mgmt Server>            | Name or IP address of the Security Management Server or Domain Management Server.                                                                                                                                                                                                                                                                                                                                                  |
| <Username>               | User name of standard Check Point authentication method.                                                                                                                                                                                                                                                                                                                                                                           |
| <Password>               | Password of standard Check Point authentication method.                                                                                                                                                                                                                                                                                                                                                                            |
| <Appliance_Model>Cluster | Model of appliance: <ul style="list-style-type: none"> <li>■ For 1100 appliances, enter: CPSG80Cluster</li> <li>■ For 1200R appliances, enter: 1200RCluster</li> <li>■ For 1430 or 1450 appliance, enter: 1430/1450Cluster</li> <li>■ For 1470 or 1490 appliance, enter: 1470/1490Cluster</li> <li>■ For 1530 or 1550 appliance, enter: 1530/1550Cluster</li> <li>■ For 1570 or 1590 appliance, enter: 1570/1590Cluster</li> </ul> |

| <MainIPAddress>          | Main IP address of cluster.                                                                                                                                                                                                                                                                                                                                                                                                        |
| <SuffixName>             | A suffix to be added to cluster and member Profile names.                                                                                                                                                                                                                                                                                                                                                                          |
| <SubstitutedNamePart>    | A part of the Profile name to be replaced by the suffix in the previous field.                                                                                                                                                                                                                                                                                                                                                     |
| <CaName>                 | The name of the Trusted CA object, defined in SmartConsole, to which a VPN certificate request is sent.                                                                                                                                                                                                                                                                                                                            |
| <KeyIdentifier#>         | Number to identify the specific certificate, once generated.                                                                                                                                                                                                                                                                                                                                                                       |

| Parameter                        | Description                                                         |
|----------------------------------|---------------------------------------------------------------------|
| <i>&lt;AuthorizationCode&gt;</i> | Authorization Key to be sent to CA to enable certificate retrieval. |

## Example

To add a 1450 cluster:

```
LSMcli 192.168.3.26 aa aaaa AddRobo 1430/1450Cluster cluster_  
profile 1.1.1.1 Paris
```

## Other LSMcli Commands for Small Office Appliances

- For all other commands on Small Office Appliance Gateways, replace the "VPN1" with the "CPSEG80", for all appliance types.

For example, change the profile (see ["LSMcli ModifyROBO VPN1" on page 901](#)):

- For a 1100 Security Gateway:

```
LSMcli 192.168.3.26 aa aaaa ModifyROBO CPSEG80 Paris_GW -  
P=second_small_office_profile
```

- For a 1200R Security Gateway:

```
LSMcli 192.168.3.26 aa aaaa ModifyROBO CPSEG80 Paris_GW -  
P=second_small_office_profile
```

- For all other commands on Small Office Appliance clusters, replace the "VPN1Cluster" with the "CPSEG80Cluster", for all appliance types (for example, in ["LSMcli ModifyROBO VPN1Cluster" on page 940](#)).

# Security Gateway Commands

For more information about Security Gateway, see the:

- [\*R82.10 Security Management Administration Guide\*](#)
- [\*R82.10 Security Gateway Guide\*](#)

# comp\_init\_policy

 **Important** - This section does **not** apply to Scalable Platforms (ElasticXL, Maestro, and Chassis).

## Description

Generates, loads, or removes the Initial Policy on a Security Gateway, or a Cluster Member.

Until the Security Gateway or cluster administrator installs the user-defined Security Policy on the Security Gateway or Cluster Members for the first time, security is enforced by an Initial Policy.

The Initial Policy operates by adding Check Point "implied rules" to the Default Filter to allow internal Check Point communication between the Management Server and the Security Gateway / Cluster Member.

The Initial Policy also protects a Security Gateway or Cluster Members in these cases:

- During Check Point product upgrades.
- When a SIC certificate is reset on the Security Gateway or Cluster Member.
- When Check Point product license expires.

The Security Gateway enforces the Initial until an administrator installs a user-defined policy. In subsequent boots, the Security Gateway loads the user-defined policy immediately after the Default Filter.

 **Important** - In a Cluster, you must configure all the Cluster Members in the same way.

## Notes:

- You must run this command from the Expert mode.
- The Initial Policy overwrites the user-defined policy.
- Output of the "cpstat -f policy fw" command (see ["cpstat" on page 1033](#)) shows the name of this policy as "InitialPolicy".
- Security Gateway, or Cluster Member stores the installed Access Control Policy in these directories:
  - \$FWDIR/state/\_\_\_tmp/FW1/
  - \$FWDIR/state/local/FW1/
  - \$FWDIR/state/<Name of Cluster Object>/FW1/
- Refer to these related commands:
  - ["control\\_bootsec" on page 979](#)
  - ["fwboot bootconf" on page 1300](#)
  - ["fw defaultgen" on page 1152](#)
  - ["fwboot default" on page 1313](#)

## Syntax

```
[Expert@HostName:0]# $FWDIR/bin/comp_init_policy [-u | -U]
```

```
[Expert@HostName:0]# $FWDIR/bin/comp_init_policy [-g | -G]
```

## Parameters

| Parameter     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| No Parameters | The command runs with the last used parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Unloading the user-defined policy

If the installed Access Control Policy prevents administrator access to the Security Gateway or drops traffic incorrectly, you need to uninstall the current user-defined policy and install the updated policy from the Management Server.

Follow these steps to keep your Security Gateway and your networks protected when you uninstall the user-defined policy:

1. Connect to the problematic Security Gateway / each Cluster Member **through the console port**.

**Warning** - If you connect over SSH, the "Initial Policy" blocks your connection.

2. Log in to the Expert mode.
3. Back up the current user-defined policy files:

```
cd $FWDIR/state/local/  
tar cvf /var/log/FW1_Policy_Bkp.tar FW1
```

4. Remove the current user-defined policy files:

```
rm $FWDIR/state/local/FW1/*
```

5. Generate the default Check Point policy called "InitialPolicy":

```
comp_init_policy
```

6. Load the "Initial Policy":

```
fw fetch local
```

7. Make sure the "Initial Policy" is loaded:

```
cpstat -f policy fw | head -n 3
```

8. In SmartConsole, make the required changes and install the Access Control policy on the Security Gateway / Cluster.

# connection\_pipelining

## Description

Controls the HyperFlow.

For more information, see the [R82.10 Performance Tuning Administration Guide](#). > Section *HyperFlow*.

## Syntax

 **Important:**

- You must run this command in the Expert mode.
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the Gaia Portal of the applicable Security Group.
- On Scalable Platforms, use the command "g\_connection\_pipelining" with the same parameters.

```
connection_pipelining
  advanced
    allow_accelerated_pipeline
    async
    default
    prevent_accelerated_pipeline
    sleep
    sync
    wake_up
  on
  off
  heaviest_conn
  pipelined
  status
```

## Parameters

| Parameter             | Description                                                                      |
|-----------------------|----------------------------------------------------------------------------------|
| No Parameters         | Shows the built-in help.                                                         |
| connection_pipelining | Must enter this command only on Security Gateways other than Scalable Platforms. |

| Parameter                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

 **Note** - The terms Parallel Processing Engine (PPE) and Dual Mode Job Dispatcher (DMD) are used interchangeably.

### Example 1 - On a supported appliance

```
[Expert@MyGW:0]# connection_pipelining status
Status of connection pipelining:      On
Flow mode:                           Asynchronous
Status of PPE_MGR and PPE_WT:        Active
Status of accelerated pipeline:       Allowed
[Expert@MyGW:0]#
```

### Example 2 - On a non-supported appliance

```
[Expert@MyGW:0]# connection_pipelining status
Status of connection pipelining:      Off. Appliances with CPU
that does not support the AVX2 flag are not supported
[Expert@MyGW:0]#
```

# connview

## Description

A tool for advanced troubleshooting that shows information about the current connections through the Security Gateway that works in the User Space Firewall (USFW, see [sk167052](#)).

This tool shows the consolidated information about connections from various Check Point modules that processed these connections (Firewall, Streaming, Parsers, Connection Tracker, and so on).

This tool gets the data about connections from all CoreXL Firewall instances in parallel, and in small quick chunks, so the packet flow is not blocked.

## Notes:

- You can run this command in Gaia Clish or in the Expert mode.
- On Scalable Platforms, you must connect to the Gaia Portal of the applicable Security Group.
- On a VSNext Gateway / Legacy VSX Gateway, you must run this command in the context of the applicable Virtual Gateway / Virtual System:

```
vsend <ID>
```

- You can also run the corresponding Gaia API command.  
See one of these Gaia API References:
  - Online [Check Point Gaia API Reference](#) (at the top, select the correct version) v1.8 and higher - section "**Diagnostics**" > section "**Connections**" > command "show-connections".
  - Local Gaia API Reference (v1.8 and higher) on your Gaia server:  
`https://<IP Address of Gaia Server>/gaia_docs/#web/show-connections`
- This tool saves its logs in the `$FWDIR/log/connview.elg` file.  
In addition, refer to log entries "connview" in the `$FWDIR/log/fwk.elg` file.

## Syntax for Gaia Clish

```
show connview [{summary | history | verbose}]
```

## Syntax for the Expert mode

```
[Expert@GW:0]# connview {-h | -? | --help}
```

```
[Expert@GW:0]# connview --usage
```

```
[Expert@GW:0]# connview <Parameter> [{summary | verbose | history}]
```

## Parameters

# control\_bootsec

 **Important** - This section does **not** apply to Scalable Platforms (ElasticXL, Maestro, and Chassis).

## Description

Controls the boot security - loading of both the Default Filter policy (`defaultfilter`) and the Initial Policy (`InitialPolicy`) during boot on a Security Gateway, or a Cluster Member.

 **Warning** - If you disable the boot security, you leave your Security Gateway, or a Cluster Member without any protection during the boot. Before you disable the boot security, we recommend to disconnect your Security Gateway, or a Cluster Member from the network completely.

 **Important** - In a Cluster, you must configure all the Cluster Members in the same way.

## Notes:

- You must run this command from the Expert mode.
- The changes made with this command survive reboot.
- Refer to these related commands:
  - ["comp\\_init\\_policy" on page 964](#)
  - ["fwboot bootconf" on page 1300](#)
  - ["fw defaultgen" on page 1152](#)
  - ["fwboot default" on page 1313](#)

## Syntax

```
[Expert@GW:0]# $FWDIR/bin/control_bootsec [-g | -G]
```

```
[Expert@GW:0]# $FWDIR/bin/control_bootsec {-r | -R}
```

## Parameters

| Parameter                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| No<br>Parameter<br>-g<br>-G | Enables the boot security: <ol style="list-style-type: none"> <li>1. Executes the "<code>\$FWDIR/boot/fwboot bootconf set_def \$FWDIR/boot/default.bin</code>" command that updates the path to the Default Filter policy in the <code>\$FWDIR/boot/boot.conf</code> file to point to the correct policy file (<code>DEFAULT_FILTER_PATH /etc/fw.boot/default.bin</code>).</li> <li>2. Executes the "<code>\$FWDIR/bin/comp_init_policy -g</code>" command that:               <ol style="list-style-type: none"> <li>a. Removes the attribute "<b>:InitialPolicySafe (true)</b>" from the section "<b>: (FW1)</b>" in the Check Point Registry (the <code>\$CPDIR/registry/HKLM_registry.data</code> file).</li> <li>b. # cp\_conf

## Description

Configures or reconfigures a Check Point product installation.

 **Note** - The available options for each Check Point server depend on the configuration and installed products.

## Syntax on a Management Server

```
cp_conf
  -h
  admin <options>
  auto <options>
  ca <options>
  client <options>
  finger <options>
  lic <options>
  snmp <options>
```

## Syntax on a Security Gateway / each Cluster Member in Gaia Clish or the Expert mode

```
cp_conf
  -h
  adv_routing <options>
  auto <options>
  corexl <options>
  fullha <options>
  ha <options>
  intfs <options>
  lic <options>
  sic <options>
  snmp <options>
```

## Syntax on a Scalable Platform Security Group in Gaia gClish

```
cp_conf
  -h
  adv_routing <options>
  auto <options>
  corexl <options>
  fullha <options>
  ha <options>
  intfs <options>
  lic <options>
  sic <options>
  snmp <options>
```

## Syntax on a Scalable Platform Security Group in the Expert mode

```
g_all cp_conf
  -h
  adv_routing <options>
  auto <options>
  corexl <options>
  fullha <options>
  ha <options>
  intfs <options>
  lic <options>
  sic <options>
  snmp <options>
```

## Parameters

| Parameter                | Description                                                                                                                                                                                                                                                                                                                         |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -h                       | Shows the entire built-in usage.                                                                                                                                                                                                                                                                                                    |
| admin<br><options>       | Configures Check Point system administrators for the Security Management Server.<br>See <a href="#">"cp_conf admin" on page 63</a> .                                                                                                                                                                                                |
| adv_routing<br><options> | Enables or disables the Advanced Routing feature on this Security Gateway.<br> <b>Important</b> - Do not use these outdated commands. To configure Advanced Routing, see the <a href="#">R82.10 Gaia Advanced Routing Administration Guide</a> . |

| Parameter           | Description                                                                                                                                                                                                                                                            |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| auto<br><options>   | Shows and configures the automatic start of Check Point products during boot.<br>See <a href="#">"cp_conf auto" on page 66</a> .                                                                                                                                       |

| finger<br><options> | Shows the ICA's Fingerprint.<br>See <a href="#">"cp_conf finger" on page 74</a> .                                                                                                                                                                                      |
| fullha<br><options> | Manages Full High Availability Cluster.<br>See <a href="#">"cp_conf fullha" on page 992</a> .<br><b>Note</b> - This command does <b>not</b> apply to Scalable Platforms (Maestro and Chassis).                                                                         |
| ha <options>        | Enables or disables cluster membership on this Security Gateway / Cluster Member.<br>See <a href="#">"cp_conf ha" on page 993</a> .<br><b>Note</b> - This command does <b>not</b> apply to Scalable Platforms (Maestro and Chassis).                                   |
| intfs<br><options>  | Sets the topology of interfaces on a Security Gateway / Cluster Member, which you manage with SmartProvisioning.<br>See <a href="#">"cp_conf intfs" on page 995</a> .<br><b>Note</b> - This command does <b>not</b> apply to Scalable Platforms (Maestro and Chassis). |
| lic<br><options>    | Manages Check Point licenses.<br>See <a href="#">"cp_conf lic" on page 76</a> .                                                                                                                                                                                        |
| sic<br><options>    | Manages SIC on this Security Gateway / Cluster Member / Security Group.<br>See <a href="#">"cp_conf sic" on page 1000</a> .                                                                                                                                            |

| Parameter         | Description                                                                                                                                                                          |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| snmp<br><options> | Do <b>not</b> use these outdated commands.<br>To configure SNMP, see the <a href="#">R82.10 Gaia Administration Guide</a> - Chapter <i>System Management</i> - Section <i>SNMP</i> . |

# cp\_conf auto

## Description

Shows and controls which of Check Point products start automatically during boot.

-  **Note** - This command corresponds to the option **Automatic start of Check Point Products** in the "[cpconfig](#)" on page 133 menu.
-  **Note** - On a Multi-Domain Server, use the option **Automatic Start of Multi-Domain Server** in the "[mdsconfig](#)" on page 763 menu.

## Syntax on a Management Server in Gaia Clish or the Expert mode

```
cp_conf auto
    -h
    {enable | disable} <Product1> <Product2> ...
    get all
```

## Syntax on a Security Gateway / Cluster Member in Gaia Clish or the Expert mode

```
cp_conf auto
    -h
    {enable | disable} <Product1> <Product2> ...
    get all
```

## Syntax on a Scalable Platform Security Group in Gaia gClish

```
cp_conf auto
    -h
    {enable | disable} <Product1> <Product2> ...
    get all
```

## Syntax on a Scalable Platform Security Group in the Expert mode

```
g_all cp_conf auto
    -h
    {enable | disable} <Product1> <Product2> ...
    get all
```

## Parameters

| Parameter                                       | Description                                                                                                                                                                                                                 |
|-------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -h                                              | Shows the applicable built-in usage.                                                                                                                                                                                        |
| {enable   disable}<br><Product1> <Product2> ... | Controls whether the installed Check Point products start automatically during boot. This command is for Check Point use only.                                                                                              |
| get all                                         | Shows which of these Check Point products start automatically during boot: <ul style="list-style-type: none"> <li>■ Check Point Security Gateway</li> <li>■ QoS (former FloodGate-1)</li> <li>■ SmartEvent Suite</li> </ul> |

## Example from a Security Management Server

```
[Expert@MGMT:0]# cp_conf auto get all
Check Point Security Gateway is not installed

QoS is not installed

The SmartEvent Suite will start automatically at boot time.

[Expert@MGMT:0]#
```

## Example from a Security Gateway

```
[Expert@GW:0] cp_conf auto get all
The Check Point Security Gateway will start automatically at boot time.

QoS will start automatically at boot time.

SmartEvent Suite is not installed.

[Expert@GW:0]#
```

# cp\_conf corexl

## Description

Enables or disables CoreXL.

For more information, see the [R82.10 Performance Tuning Administration Guide](#).

### Important:

- This command is for Check Point use only.  
To configure CoreXL, use the **Check Point CoreXL** option in the "*cpconfig*" on [page 1002](#) menu.
- After all changes in CoreXL configuration on the Security Gateway / Cluster Member / Security Group, you must reboot it.
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the Gaia Portal of the applicable Security Group.

## Syntax on a Security Gateway / Cluster Member in Gaia Clish or the Expert mode

- To enable CoreXL with 'n' IPv4 Firewall instances and optionally 'k' IPv6 Firewall instances:

```
cp_conf corexl [-v] enable [n] [-6 k]
```

- To disable CoreXL:

```
cp_conf corexl [-v] disable
```

## Syntax on a Scalable Platform Security Group in Gaia gClish

- To enable CoreXL with 'n' IPv4 Firewall instances and optionally 'k' IPv6 Firewall instances:

```
cp_conf corexl [-v] enable [n] [-6 k]
```

- To disable CoreXL:

```
cp_conf corexl [-v] disable
```

## Syntax on a Scalable Platform Security Group in the Expert mode

- To enable CoreXL with 'n' IPv4 Firewall instances and optionally 'k' IPv6 Firewall instances:

```
g_all cp_conf corexl [-v] enable [n] [-6 k]
```

- To disable CoreXL:

```
g_all cp_conf corexl [-v] disable
```

The related command is: ["fwboot corexl" on page 1304](#).

## Parameters

| Parameter | Description                                           |
|-----------|-------------------------------------------------------|
| -v        | Leaves the high memory (vmalloc) unchanged.           |
| n         | Denotes the number of IPv4 CoreXL Firewall instances. |
| k         | Denotes the number of IPv6 CoreXL Firewall instances. |

## Example

Currently, the Security Gateway runs two IPv4 CoreXL Firewall instances (`KERN_INSTANCE_NUM = 2`).

We change the number of IPv4 CoreXL Firewall instances to three.

```
[Expert@MyGW:0]# fw ctl multik stat
ID | Active | CPU | Connections | Peak
-----
0 | Yes | 2 | 7 | 28
1 | Yes | 1 | 0 | 11
[Expert@MyGW:0]#
[Expert@MyGW:0]# cat /etc/fw.boot/boot.conf
CTL_IPFORWARDING 1
DEFAULT_FILTER_PATH 0
KERN_INSTANCE_NUM 2
COREXL_INSTALLED 1
KERN6_INSTANCE_NUM 2
IPV6_INSTALLED 0
CORE_OVERRIDE 4
[Expert@MyGW:0]#
[Expert@MyGW:0]# cp_conf corexl -v enable 3
[Expert@MyGW:0]#
[Expert@MyGW:0]# cat /etc/fw.boot/boot.conf
CTL_IPFORWARDING 1
DEFAULT_FILTER_PATH 0
KERN_INSTANCE_NUM 3
COREXL_INSTALLED 1
KERN6_INSTANCE_NUM 2
IPV6_INSTALLED 0
CORE_OVERRIDE 4
[Expert@MyGW:0]#
[Expert@MyGW:0]# reboot
.. .. .
[Expert@MyGW:0]# fw ctl multik stat
ID | Active | CPU | Connections | Peak
-----
0 | Yes | 3 | 7 | 28
1 | Yes | 2 | 0 | 11
2 | Yes | 1 | 4 | 10
[Expert@MyGW:0]#
```

## cp\_conf fullha

 **Important** - This command does **not** apply to Scalable Platforms (Maestro and Chassis).

### Description

Manages the state of the Full High Availability Cluster:

- Enables the Full High Availability Cluster
- Disables the Full High Availability Cluster
- Deletes the Full High Availability peer
- Shows the Full High Availability state

 **Important** - To configure a Full High Availability cluster, follow the [R82.10 Installation and Upgrade Guide](#).

### Syntax

```
cp_conf fullha
    enable
    del_peer
    disable
    state
```

### Parameters

| Parameter | Description                                                     |
|-----------|-----------------------------------------------------------------|
| enable    | Enables the Full High Availability on this computer.            |
| del_peer  | Deletes the Full High Availability peer from the configuration. |
| disable   | Disables the Full High Availability on this computer.           |
| state     | Shows the Full High Availability state on this computer.        |

### Example

```
[Expert@Cluster_Member:0]# cp_conf fullha state
FullHA is currently enabled
[Expert@Cluster_Member:0]#
```

## cp\_conf ha

 **Important** - This command does **not** apply to Scalable Platforms (Maestro and Chassis).

### Description

Enables or disables cluster membership on this Security Gateway.

 **Important** - This command is for Check Point use only. To configure cluster membership, you must use the ["cpconfig" on page 1002](#) command. For more information, see the [R82.10 ClusterXL Administration Guide](#).

### Syntax

```
cp_conf ha {enable | disable} [norestart]
```

### Parameters

| Parameter | Description                                                                                                                                                                                            |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| enable    | Enables cluster membership on this Security Gateway. This command is equivalent to the option <b>Enable cluster membership for this gateway</b> in the <a href="#">"cpconfig" on page 1002</a> menu.   |
| disable   | Disables cluster membership on this Security Gateway. This command is equivalent to the option <b>Disable cluster membership for this gateway</b> in the <a href="#">"cpconfig" on page 1002</a> menu. |
| norestart | <b>Optional:</b> Specifies to apply the configuration change without the restart of Check Point services. The new configuration takes effect only after reboot.                                        |

### Example 1 - Enable the cluster membership without restart of Check Point services

```
[Expert@MyGW:0]# cp_conf ha enable norestart

Cluster membership for this gateway was enabled successfully
Important: This change will take effect after reboot.

[Expert@MyGW:0]#
```

## Example 2 - Disable the cluster membership without restart of Check Point services

```
[Expert@MyGW:0]# cp_conf ha disable norestart
cpwd_admin:
Process CPHAMCSET process has been already terminated

Cluster membership for this gateway was disabled successfully
Important: This change will take effect after reboot.

[Expert@MyGW:0]#
```

# cp\_conf intfs

 **Important** - This command does **not** apply to Scalable Platforms (Maestro and Chassis).

## Description

Sets the topology of interfaces on a Security Gateway, which you manage with SmartProvisioning.

For more information, see the [R82.10 SmartProvisioning Administration Guide](#).

## Syntax

```
cp_conf intfs
  get
  set
      auxiliary <Name of Interface>
      DMZ <Name of Interface>
      external <Name of Interface>
      internal <Name of Interface>
```

## Parameters

| Parameter | Description                                                                                                                                                         |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| get       | Shows the list of configured interfaces.                                                                                                                            |
| set       | Configures the topology of the specified interface: <ul style="list-style-type: none"><li>■ auxiliary</li><li>■ DMZ</li><li>■ external</li><li>■ internal</li></ul> |

## cp\_conf lic

### Description

Shows, adds and deletes Check Point licenses.

 **Note** - This command corresponds to the option **Licenses and contracts** in the *"cpconfig" on page 133* menu.

 **Note:**  
On a Multi-Domain Server, you must run this command in the context of the applicable Domain Management Server:

```
mdsenv <IP Address or Name of Domain Management Server>
```

## Syntax on a Management Server in Gaia Clish or the Expert mode

```
cp_conf lic
-h
add -f <Full Path to License File>
add -m <Host> <Date> <Signature Key> <SKU/Features>
del <Signature Key>
get [-x]
```

## Syntax on a Security Gateway / Cluster Member in Gaia Clish or the Expert mode

```
cp_conf lic
-h
add -f <Full Path to License File>
add -m <Host> <Date> <Signature Key> <SKU/Features>
del <Signature Key>
get [-x]
```

## Syntax on a Scalable Platform Security Group in Gaia gClish

```
cp_conf lic
-h
add -f <Full Path to License File>
add -m <Host> <Date> <Signature Key> <SKU/Features>
del <Signature Key>
get [-x]
```

## Syntax on a Scalable Platform Security Group in the Expert mode

```
g_all cp_conf lic
-h
add -f <Full Path to License File>
add -m <Host> <Date> <Signature Key> <SKU/Features>
del <Signature Key>
get [-x]
```

## Parameters

| Parameter                                                 | Description                                                                                                                                                                                                                                             |
|-----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -h                                                        | Shows the applicable built-in usage.                                                                                                                                                                                                                    |
| add -f <Full Path to License File>                        | <p>Adds a license from the specified Check Point license file.</p> <p>You get this license file in the <a href="#">Check Point User Center</a>.</p> <p>This is the same command as the "<a href="#">cplic db_add</a>" on <a href="#">page 143</a>.</p>  |
| add -m <Host> <Date><br><Signature Key><br><SKU/Features> | <p>Adds the license manually.</p> <p>You get these license details in the <a href="#">Check Point User Center</a>.</p> <p>This is the same command as the "<a href="#">cplic db_add</a>" on <a href="#">page 143</a>.</p>                               |
| del <Signature Key>                                       | <p>Delete the license based on its signature.</p> <p>This is the same command as the "<a href="#">cplic del</a>" on <a href="#">page 148</a>.</p>                                                                                                       |
| get [-x]                                                  | <p>Shows the local installed licenses.</p> <p>If you specify the "-x" parameter, output also shows the signature key for every installed license.</p> <p>This is the same command as the "<a href="#">cplic print</a>" on <a href="#">page 152</a>.</p> |

### Example 1 - Adding the license from the file

```
[Expert@HostName:0]# cp_conf lic add -f ~/License.lic
License was installed successfully.
[Expert@HostName:0]#

[Expert@HostName:0]# cp_conf lic get
Host           Expiration   Signature                                     Features
192.168.3.28    25Aug2019    xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx    CPMP-XXX
[Expert@HostName:0]#
```

## Example 2 - Adding the license manually

```
[Expert@MyHostName:0]# cp_conf lic add -m MyHostName 25Aug2019
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx CPMP-XXX
License was successfully installed
[Expert@MyHostName:0]#

[Expert@MyHostName:0]# cp_conf lic get
Host          Expiration    Signature                                     Features
192.168.3.28   25Aug2019          xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx CPMP-XXX
[Expert@MyHostName:0]#
```

# cp\_conf sic

## Description

Manages SIC on the Security Gateway.

For additional information, see [sk65764: How to reset SIC](#).

**Note** - This command corresponds to the option **Secure Internal Communication** in the "*cpconfig*" on page 1002 menu.

## Syntax on a Security Gateway / Cluster Member in Gaia Clish or the Expert mode

```
cp_conf
    -h
    sic
        cert_pull <Management Server> <DAIP GW object>
        init <Activation Key> [norestart]
        state
```

## Syntax on a Scalable Platform Security Group in Gaia gClish

```
cp_conf
    -h
    sic
        cert_pull <Management Server> <DAIP GW object>
        init <Activation Key> [norestart]
        state
```

## Syntax on a Scalable Platform Security Group in the Expert mode

```
g_all cp_conf
    -h
    sic
        cert_pull <Management Server> <DAIP GW object>
        init <Activation Key> [norestart]
        state
```

## Parameters

| Parameter                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -h                                                   | Shows the built-in usage.                                                                                                                                                                                                                                                                                                                                                                                           |
| cert_pull<br><Management Server><br><DAIP GW object> | For DAIP Security Gateways, pulls a SIC certificate from the specified Management Server for the specified DAIP Security Gateway: <ul style="list-style-type: none"> <li>▪ &lt;Management Server&gt; - IPv4 address or HostName of the Security Management Server or Domain Management Server</li> <li>▪ &lt;DAIP GW object&gt; - Name of the DAIP Security Gateway object as configured in SmartConsole</li> </ul> |
| init <Activation Key> [norestart]                    | Resets the one-time SIC activation key.<br>The optional parameter "norestart" specifies not to restart Check Point services.                                                                                                                                                                                                                                                                                        |
| state                                                | Shows the current state of the SIC Trust.                                                                                                                                                                                                                                                                                                                                                                           |

## Example

```
[Expert@MyGW:0]# cp_conf sic state
Trust State: Trust established
[Expert@MyGW:0]#
```

# cpconfig

## Description

This command starts the Check Point Configuration Tool.

This tool configures specific settings for the installed Check Point products.

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.

## Syntax on a Security Gateway / Cluster Member in Gaia Clish or the Expert mode

```
cpconfig
```

## Syntax on a Scalable Platform Security Group in Gaia gClish or the Expert mode

```
cpconfig
```

## Menu Options

 **Note** - The options shown depend on the configuration and installed products.

| Menu Option            | Description                                                                                                                                                                                |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Licenses and contracts | Manages Check Point licenses and contracts on this Security Gateway or Cluster Member.                                                                                                     |
| SNMP Extension         | Obsolete. Do <b>not</b> use this option anymore.<br>To configure SNMP, see the <a href="#">R82.10 Gaia Administration Guide</a> - Chapter <i>System Management</i> - Section <i>SNMP</i> . |
| PKCS#11 Token          | Register a cryptographic token, for use by Gaia Operating System.<br>See details of the token, and test its functionality.                                                                 |
| Random Pool            | Configures the RSA keys, to be used by Gaia Operating System.                                                                                                                              |

| Menu Option                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Example 1 - Menu on a single Security Gateway

```
[Expert@MySingleGW:0]# cpconfig
This program will let you re-configure
your Check Point products configuration.

Configuration Options:
-----
(1) Licenses and contracts
(2) SNMP Extension
(3) PKCS#11 Token
(4) Random Pool
(5) Secure Internal Communication
(6) Enable cluster membership for this gateway
(7) Check Point CoreXL
(8) Automatic start of Check Point Products

(9) Exit

Enter your choice (1-9) :
```

## Example 2 - Menu on a Cluster Member

```
[Expert@MyClusterMember:0]# cpconfig
This program will let you re-configure
your Check Point products configuration.

Configuration Options:
-----
(1) Licenses and contracts
(2) SNMP Extension
(3) PKCS#11 Token
(4) Random Pool
(5) Secure Internal Communication
(6) Disable cluster membership for this gateway
(7) Enable Check Point Per Virtual System State
(8) Enable Check Point ClusterXL for Bridge Active/Standby
(9) Check Point CoreXL
(10) Automatic start of Check Point Products

(11) Exit

Enter your choice (1-11) :
```

# cplic

## Description

The `cplic` command manages Check Point licenses.

You can run this command:

- On a Security Gateway / Cluster Member in Gaia Clish or the Expert mode
- On a Scalable Platform Security Group in Gaia gClish or the Expert mode

License Management is divided into three types of commands:

| Licensing Commands          | Applies To                                                                                    | Description                                                                                                                                                              |
|-----------------------------|-----------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Local licensing commands    | Management Servers, Security Gateways, Cluster Members, and Scalable Platform Security Groups | You execute these commands locally on the Check Point servers and gateways.                                                                                              |
| Remote licensing commands   | Management Servers only                                                                       | You execute these commands on the Security Management Server or Domain Management Server.<br>These changes apply to the managed Security Gateways and Cluster Members.   |
| License Repository commands | Management Servers only                                                                       | You execute these commands on the Security Management Server or Domain Management Server.<br>These changes apply to the licenses stored in the local license repository. |

For more about managing licenses, see the [R82.10 Security Management Administration Guide](#).

## Syntax for Local Licensing on a Security Gateway / Cluster Member / Security Group

```
cplic [-d]
      {-h | -help}
      check <options>
      contract <options>
      del <options>
      print <options>
      put <options>
```

### Parameters

| Parameter             | Description                                                                                                                                                                                                                                                                                                                              |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d                    | Runs the command in debug mode.<br>Use only if you troubleshoot the command itself.<br> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session. |
| {-h   -help}          | Shows the applicable built-in usage.                                                                                                                                                                                                                                                                                                     |
| check<br><options>    | Confirms that the license includes the feature on the local Security Gateway or Security Management Server.<br>See <a href="#">"cplic check" on page 1008</a> .                                                                                                                                                                          |
| contract<br><options> | Manages (deletes and installs) the Check Point Service Contract on the local Check Point server.<br>See <a href="#">"cplic contract" on page 1010</a> .                                                                                                                                                                                  |
| del<br><options>      | Deletes a Check Point license on a host, including unwanted evaluation, expired, and other licenses.<br>See <a href="#">"cplic del" on page 1012</a> .                                                                                                                                                                                   |
| print<br><options>    | Prints details of the installed Check Point licenses on the local Check Point server.<br>See <a href="#">"cplic print" on page 1013</a> .                                                                                                                                                                                                |
| put<br><options>      | Installs and attaches licenses on a Check Point server.<br>See <a href="#">"cplic put" on page 1016</a> .                                                                                                                                                                                                                                |

# cplic check

## Description

Confirms that the license includes the feature on the local Security Gateway or Management Server. See [sk66245](#).

## Syntax

```
cplic check {-h | -help}
```

```
cplic [-d] check [-p <Product>] [-v <Version>] [{-c | -count}] [-t  
<Date>] [{-r | -routers}] [{-S | -SRusers}] <Feature>
```

You can run this command:

- On a Management Server / Security Gateway / Cluster Member in Gaia Clish or the Expert mode
- On a Scalable Platform Security Group in Gaia gClish or the Expert mode

## Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {-h   -help}    | Shows the applicable built-in usage.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

[Expert@GW]#
```

# cplic contract

## Description

Deletes the Check Point Service Contract on the local Check Point server.

Installs the Check Point Service Contract on the local Check Point server.

## Note

- For more information about Service Contract files, see [sk33089: What is a Service Contract File?](#)
- If you install a Service Contract on a managed Security Gateway / Cluster Member / Scalable Platform Security Group, you must update the license repository on the applicable Management Server - either with the "*cplic get*" on [page 150](#) command, or in SmartUpdate.

## Syntax

```
cplic contract -h

cplic [-d] contract
    del
        -h
        <Service Contract ID>
    put
        -h
        [{-o | -overwrite}] <Service Contract File>
```

You can run this command:

- On a Management Server / Security Gateway / Cluster Member in Gaia Clish or the Expert mode
- On a Scalable Platform Security Group in Gaia gClish or the Expert mode

## Parameters

| Parameter                                  | Description                                                                                                                                                                                                                                                          |
|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{-h   -help}</code>                  | Shows the applicable built-in usage.                                                                                                                                                                                                                                 |
| <code>-d</code>                            | <p>Runs the command in debug mode.<br/>Use only if you troubleshoot the command itself.</p> <p>★ <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p> |
| <code>del</code>                           | Deletes the Service Contract from the <code>\$CPDIR/conf/cp.contract</code> file on the local Check Point server.                                                                                                                                                    |
| <code>put</code>                           | Merges the Service Contract to the <code>\$CPDIR/conf/cp.contract</code> file on the local Check Point server.                                                                                                                                                       |
| <code>&lt;Service Contract ID&gt;</code>   | ID of the Service Contract.                                                                                                                                                                                                                                          |
| <code>{-o   -overwrite}</code>             | Specifies to overwrite the current Service Contract.                                                                                                                                                                                                                 |
| <code>&lt;Service Contract File&gt;</code> | <p>Path to and the name of the Service Contract file.<br/>First, you must download the Service Contract file from your <a href="#">Check Point User Center</a> account.</p>                                                                                          |

# cplic del

## Description

Deletes a Check Point license on a host, including unwanted evaluation, expired, and other licenses.

This command can delete a license on both local server, and on remote managed servers.

## Syntax

```
cplic del {-h | -help}
```

```
cplic [-d] del [-F <Output File>] <Signature> <Object Name>
```

You can run this command:

- On a Management Server / Security Gateway / Cluster Member in Gaia Clish or the Expert mode
- On a Scalable Platform Security Group in Gaia gClish or the Expert mode

## Parameters

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {-h   -help}     | Shows the applicable built-in usage.                                                                                                                                                                                                                                                                                                       |
| -d               | Runs the command in debug mode.<br>Use only if you troubleshoot the command itself.<br> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session. |
| -F <Output File> | Saves the command output to the specified file.                                                                                                                                                                                                                                                                                            |
| <Signature>      | The signature string within the license.<br>To see the license signature string, run the <a href="#">"cplic print" on page 152</a> command.                                                                                                                                                                                                |
| <Object Name>    | The name of the Security Gateway / Cluster Member object as configured in SmartConsole.                                                                                                                                                                                                                                                    |

# cplic print

## Description

Prints details of the installed Check Point licenses on the local Check Point server.

### Notes:

- On a Security Gateway / Cluster Member / Scalable Platform Security Group, this command prints all installed licenses (both Local and Central).
- Before installing a valid license, and after you establish SIC between this Security Gateway / Cluster Member and its Management Server, this command shows the trial license.

## Syntax

```
cplic print {-h | -help}
```

```
cplic [-d] print[{-n | -noheader}] [-x] [{-t | -type}] [-F <Output File>] [{-p | -preatures}] [-D]
```

You can run this command:

- On a Management Server / Security Gateway / Cluster Member in Gaia Clish or the Expert mode
- On a Scalable Platform Security Group in Gaia gClish or the Expert mode

## Parameters

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {-h   -help}     | Shows the applicable built-in usage.                                                                                                                                                                                                                                                                                                       |
| -d               | Runs the command in debug mode.<br>Use only if you troubleshoot the command itself.<br> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session. |
| {-n   -noheader} | Prints licenses without the output header.                                                                                                                                                                                                                                                                                                 |
| -x               | Prints licenses and their signature.                                                                                                                                                                                                                                                                                                       |
| {-t   -type}     | Prints licenses and their type: Central or Local.                                                                                                                                                                                                                                                                                          |
| -F <Output File> | Saves the command output to the specified file.                                                                                                                                                                                                                                                                                            |

| Parameter         | Description                                                                                                                                                                                                                            |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {-p   -preatures} | Prints licenses and their primitive features.<br> <b>Best Practice</b> - Use this syntax:<br><div>cplic print -n -p   tr ' ' '\n'  <br/>sort -u</div> |
| -D                | On a Multi-Domain Server, prints only Domain licenses.                                                                                                                                                                                 |

Example 1

```
[Expert@HostName:0]# cplic print
Host      Expiration  Features
192.168.3.28  25Aug2019  CPMP-XXX  CK-XXXXXXXXXXXXX
[Expert@HostName:0]#
```

Example 2

```
[Expert@HostName:0]# cplic print -n
192.168.3.28  25Aug2019  CPMP-XXX  CK-XXXXXXXXXXXXX
[Expert@HostName:0]#
```

Example 3

```
[Expert@HostName:0]# cplic print -x
Host      Expiration  Signature                                     Features
192.168.3.28  25Aug2019  xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx  CPMP-XXX  CK-XXXXXXXXXXXXX
[Expert@HostName:0]#
```

Example 4

```
[Expert@HostName:0]# cplic print -t
Type      Host      Expiration  Features
central   192.168.3.28  25Aug2019  CPMP-XXX  CK-XXXXXXXXXXXXX
[Expert@HostName:0]#
```

## Example 5

```
[Expert@HostName:0]# cplic print -t
Host          Expiration    Features
192.168.3.28   25Aug2019      CPMP-XXX  CK-XXXXXXXXXXXX fw1:6.0:swb fw1:6.0:zp fw1:6.0:ctnt ...
[Expert@HostName:0]#

[Expert@HostName:0]# cplic print -n -p | tr ' ' '\n' | sort -u

25Aug2019
192.168.3.28

[Expert@HostName:0]#
```

# cplic put

## Description

Installs one or more Local licenses on a Check Point server.

**Note** - You get the license details in the [Check Point User Center](#).

## Syntax

```
cplic put {-h | -help}
```

```
cplic [-d] put [{-o | -overwrite}] [{-c | -check-only}] [{-s | -select}] [-F <Output File>] [{-P | -Pre-boot}] [{-k | -kernel-only}] -l <License File> [<Host>] [<Expiration Date>] [<Signature>] [<SKU/Features>]
```

You can run this command:

- On a Management Server / Security Gateway / Cluster Member in Gaia Clish or the Expert mode
- On a Scalable Platform Security Group in Gaia gClish or the Expert mode

## Parameters

| Parameter          | Description                                                                                                                                                                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {-h   -help}       | Shows the applicable built-in usage.                                                                                                                                                                                                                   |
| -d                 | Runs the command in debug mode.<br>Use only if you troubleshoot the command itself.<br><b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session. |
| {-o   -overwrite}  | On a Security Gateway / Cluster Member / Scalable Platform Security Group, this command erases only the local licenses, but not central licenses that are installed remotely.                                                                          |
| {-c   -check-only} | Verifies the license. Checks if the IP of the license matches the Check Point server and if the signature is valid.                                                                                                                                    |
| {-s   -select}     | Selects only the local license whose IP address matches the IP address of the Check Point server.                                                                                                                                                      |

| Parameter                            | Description                                                                                                                                                                                                                           |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-F &lt;Output File&gt;</code>  | Saves the command output to the specified file.                                                                                                                                                                                       |
| <code>{-P   -Pre-boot}</code>        | Use this option after you have upgraded and before you reboot the Check Point server.<br>Use of this option will prevent certain error messages.                                                                                      |
| <code>{-K   -kernel-only}</code>     | Pushes the current valid licenses to the kernel.<br>For use by Check Point Support only.                                                                                                                                              |
| <code>-l &lt;License File&gt;</code> | Name of the file that contains the license.                                                                                                                                                                                           |
| <code>&lt;Host&gt;</code>            | Hostname or IP address of the Security Gateway / Cluster Member / Scalable Platform Security Group for a local license.<br>Hostname or IP address of the Security Management Server / Domain Management Server for a central license. |
| <code>&lt;Expiration Date&gt;</code> | The license expiration date.                                                                                                                                                                                                          |
| <code>&lt;Signature&gt;</code>       | The signature string within the license.<br>Case sensitive. The hyphens are optional.                                                                                                                                                 |
| <code>&lt;SKU/Features&gt;</code>    | The SKU of the license summarizes the features included in the license.<br>For example: CPSUITE-EVAL-3DES-vNG                                                                                                                         |

Copy and paste the parameters from the license received from the User Center:

| Parameter       | Description                                                                                                                                                                                     |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| host            | The IPv4 address of the external interface (in quad-dot notation).                                                                                                                              |
| expiration date | The license expiration date. It can be <code>never</code> .                                                                                                                                     |
| signature       | The license signature string.<br>Case sensitive. The hyphens are optional.                                                                                                                      |
| SKU/features    | A string listing the SKU and the Certificate Key of the license.<br>The SKU of the license summarizes the features included in the license.<br>For example: CPSB-SWB CPSB-ADNC-M CK0123456789ab |

## Example

```
[Expert@HostName:0]# cplic put -l License.lic
Host Expiration SKU
192.168.2.3 14Jan2016  CPSB-SWB  CPSB-ADNC-M  CK0123456789ab
[Expert@HostName:0]#
```

# cpmonitor

## Description

The CPMonitor tool analyzes traffic captured by the TCPdump, the Check Point FW Monitor (see ["fw monitor" on page 1187](#)).

The CPMonitor tool parses the input traffic capture file and extracts valuable information from it, including:

- Overall traffic statistics (pps, cps, concurrent, throughput)
- Top connections, top servers and top services
- Detailed connections, servers and services (with packet size distribution)
- Per second analysis

When analyzing the captured traffic, the CPMonitor tool can run in one of these modes: Complete or Navigate, producing different insights.

For more information, see [sk141412](#).

### Important:

- You must run this command in the Expert mode.
- On Scalable Platforms, you must connect to the Gaia Portal of the applicable Security Group.

## Syntax

```
cpmonitor [<Parameters>] /<Path To>/<Traffic Capture File>  
cpmonitor --version
```

## Parameters

You can specify several parameters.

| Parameter                         | Description                                                    |
|-----------------------------------|----------------------------------------------------------------|
| /<Path To>/<Traffic Capture File> | Specifies the path to the traffic capture file to be analyzed. |

| Parameter                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-c &lt;Size of Connections Table&gt;</code>             | Specifies the size of the Connections Table - an integer number of entries that the Connections Table can hold.<br>Default = 10,000,000<br>Maximum = 200,000,000                                                                                                                                                                                                                                                                                                           |
| <code>-g /&lt;Path To&gt;/&lt;Graph File&gt;</code>           | Saves a timeline graph in the specified file (automatically adds the CSV extension):<br><code>/&lt;Path To&gt;/&lt;Graph File&gt;.csv</code>                                                                                                                                                                                                                                                                                                                               |
| <code>-n /&lt;Path To&gt;/&lt;Traffic Capture File&gt;</code> | Navigates through the traffic capture file.<br>Creates a report for the first second of the traffic capture file, allows navigation across the file, and increases the window size to cover more than one second.<br>This mode allows better understanding of traffic bursts and peaks, which may have occurred during the capture.<br> <b>Note</b> - Press "h" to see available options. |
| <code>-o /&lt;Path To&gt;/&lt;Output File&gt;</code>          | Saves the report in the specified file (automatically adds the TXT extension):<br><code>/&lt;Path To&gt;/&lt;Output File&gt;.txt</code>                                                                                                                                                                                                                                                                                                                                    |
| <code>-q</code>                                               | Quiet mode, no output on stdout.<br>Only saves the information in the output file(s).                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>-s {p   t}</code>                                       | Configures the sorting method for top entities: <ul style="list-style-type: none"> <li>▪ p - Sort by packets (default)</li> <li>▪ t - Sort by throughput</li> </ul>                                                                                                                                                                                                                                                                                                        |
| <code>-t &lt;Name&gt;</code>                                  | Saves the entire tables in these files:<br><code>/&lt;Path To&gt;/&lt;Name&gt;_&lt;Table Name&gt;.csv</code><br>This parameter creates detailed CSV files that contain all the connections, servers, and services.<br>This gives you a complete picture of the entire traffic (not just the top connections).                                                                                                                                                              |

| <code>--version</code>                                        | Shows the "cpmonitor" version number.                                                                                                                                                                                                                                                                                                                                                                                                                                      |

# cppcap

## Description

The CPPCAP (Check Point PCAP) is a traffic capture tool that provides the most relevant outputs and is similar to the Linux tool TCPdump.

Check Point created this tool to resolve various issues in the Linux tool TCPdump that significantly increased CPU load on Check Point Security Gateways.

### Notes:

- The CPPCAP tool also captures traffic that is accelerated in SecureXL.
- For more information, see [sk141412](#).
- Also, refer to *"fw monitor" on page 1187*.

### Important:

- You must run this command in the Expert mode.
- On Scalable Platforms, you must connect to the Gaia Portal of the applicable Security Group.
- On Scalable Platforms, this command does not support the "g\_all" command (nor the "g\_cppcap" command).  
You must move to the context of each relevant Security Group Member and run the "cppcap" command.

## Syntax

```
cppcap -h
```

```
cppcap
  -b <Limit of Bytes>
  -c {0 | <Limit of Bytes in Frame>}
  -d {in | out}
  -D
  -f "<Filter>"
  {-i <Interface> | -I <Interface>}
  -N
  -o <Output File> [-w <Limit of File Size>[{K|M|G}] [-W
<Limit of Files>]]
  -p <Limit of Frames>
  -P
  -Q
  -T
  {-v <VSID to Include> | -V <VSID to Exclude>}
```

## Parameters

You can specify several parameters.

| Parameter                                             | Description                                                                                                                                                                                                                                                                                                  |
|-------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-h</code>                                       | Shows the built-in help.                                                                                                                                                                                                                                                                                     |
| <code>-b &lt;Limit of Bytes&gt;</code>                | Specifies the maximum number of bytes to capture before the tool stops.                                                                                                                                                                                                                                      |
| <code>-c {0   &lt;Limit of Bytes in Frame&gt;}</code> | Specifies the maximum number of bytes to capture in each frame.<br>Default: 96.<br>To remove the limit, enter the value 0 (zero).                                                                                                                                                                            |
| <code>-D</code>                                       | Captures verbose data for the Datalink Layer (Layer 2). <ul style="list-style-type: none"> <li>▪ This parameter applies only if you do not use the parameter <code>"-o"</code> and show the captured traffic on the screen.</li> <li>▪ This parameter does not support dynamic routing protocols.</li> </ul> |
| <code>-d {in   out}</code>                            | Captures traffic only in the specified direction: <ul style="list-style-type: none"> <li>▪ <code>in</code> - Only inbound</li> <li>▪ <code>out</code> - Only outbound</li> </ul> <p>By default, this tool captures traffic in both directions of the connection.</p>                                         |
| <code>-f "&lt;Filter&gt;"</code>                      | Specifies the filter expression for traffic capture.<br>See <a href="#">pcap-filter(7)</a> .                                                                                                                                                                                                                 |
| <code>-i &lt;Interface&gt;</code>                     | Captures traffic only in the specified interface.<br>This parameter is mutually exclusive with the parameter <code>"-I &lt;Interface&gt;"</code> .                                                                                                                                                           |
| <code>-I &lt;Interface&gt;</code>                     | Captures traffic only in all interfaces, except the specified interface.<br>This parameter is mutually exclusive with the parameter <code>"-i &lt;Interface&gt;"</code> .                                                                                                                                    |

| Parameter                                                       | Description                                                                                                                                                                                                                                                                                                                            |
|-----------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -N                                                              | <p>Captures verbose data for the Network Layer (Layer 3).</p> <ul style="list-style-type: none"> <li>■ This parameter applies only if you do not use the parameter "-o" and show the captured traffic on the screen.</li> <li>■ This parameter does not support dynamic routing protocols.</li> </ul>                                  |
| -o <Output File> [-w <Limit of Files> [-W <Limit of File Size>] | <p>Specifies the path and the name of the output file.</p> <ul style="list-style-type: none"> <li>■ If you do not specify this file, the tool shows the captured traffic on the screen.</li> <li>■ To control the rotation of output files, use the parameters "-w &lt;Limit of Files&gt;" and "-W &lt;Limit of Files&gt;".</li> </ul> |
| -P                                                              | Captures verbose processor ID.                                                                                                                                                                                                                                                                                                         |
| -p <Limit of Frames>                                            | Specifies the maximum number of frames to capture before the tool stops.                                                                                                                                                                                                                                                               |
| -Q                                                              | <p>Remove the timestamp from the traffic capture.</p> <p>This parameter applies only if you do not use the parameter "-o" and show the captured traffic on the screen.</p>                                                                                                                                                             |
| -T                                                              | <p>Captures verbose data for the Transport Layer (Layer 4).</p> <ul style="list-style-type: none"> <li>■ This parameter applies only if you do not use the parameter "-o" and show the captured traffic on the screen.</li> <li>■ This parameter does not support dynamic routing protocols.</li> </ul>                                |

You can use this parameter "-W" only together with the parameters "-o &lt;Output File&gt; -w &lt;Limit of File Size&gt;[{K M G}]".</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Examples

- Example 1 - Capture ARP and traffic with a specific host 192.168.3.57:

```
cppcap -i eth0 -f "arp and host 192.168.3.57" -o /var/log/capture.pcap
```

- Example 2 - Capture traffic with a specific host 192.168.3.57 - exclude SSH:

```
cppcap -i eth0 -f "host 192.168.3.57 and not tcp port 22"
```

- Example 3 - Capture ICMP with a specific host 192.168.3.57 - only in Virtual System 3:

```
cppcap -i eth0 -f "icmp and host 192.168.3.57" -v 3 -o /var/log/capture.pcap
```

- Example 4 - Capture traffic with a specific host 192.168.3.57 - save traffic in a maximum of 10 rotated output files, each file has a maximum size of 1 gigabyte:

```
cppcap -i eth0 -f "host 192.168.3.57" -W 10 -w 1G -o /var/log/capture.pcap
```

# cpprod\_util

## Description

This utility works with Check Point Registry (\$CPDIR/registry/HKLM\_registry.data) without manually opening it:

- Shows which Check Point products and features are enabled on this Check Point server.
- Enables and disables Check Point products and features on this Check Point server.

## Syntax on a Management Server in Gaia Clish or the Expert mode

```
cpprod_util CPPROD_GetValue "<Product>" "<Parameter>" {0|1}
```

```
cpprod_util CPPROD_SetValue "<Product>" "<Parameter>" {1|4}  
"<Value>" {0|1}
```

```
cpprod_util -dump
```

## Syntax on a Security Gateway / Cluster Member in Gaia Clish or the Expert mode

```
cpprod_util CPPROD_GetValue "<Product>" "<Parameter>" {0|1}
```

```
cpprod_util CPPROD_SetValue "<Product>" "<Parameter>" {1|4}  
"<Value>" {0|1}
```

```
cpprod_util -dump
```

## Syntax on a Scalable Platform Security Group in Gaia gClish

```
cpprod_util CPPROD_GetValue "<Product>" "<Parameter>" {0|1}
```

```
cpprod_util CPPROD_SetValue "<Product>" "<Parameter>" {1|4}  
"<Value>" {0|1}
```

```
cpprod_util -dump
```

## Syntax on a Scalable Platform Security Group in the Expert mode

```
g_all cpprod_util CPPROD_GetValue "<Product>" "<Parameter>" {0|1}
```

```
g_all cpprod_util CPPROD_SetValue "<Product>" "<Parameter>" {1|4}  
"<Value>" {0|1}
```

```
g_all cpprod_util -dump
```

## Parameters

| Parameter             | Description                                                                                                                                                                                                                                                         |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CPPROD_<br>GetValue   | Gets the configuration status of the specified product or feature: <ul style="list-style-type: none"> <li>▪ 0 - Disabled</li> <li>▪ 1 - Enabled</li> </ul>                                                                                                          |
| CPPROD_<br>SetValue   | Sets the configuration for the specified product or feature.<br> <b>Important</b> - Do not run these commands unless explicitly instructed by Check Point Support or R&D to do so. |
| "<Product<br>>"       | Specifies the product or feature.                                                                                                                                                                                                                                   |
| "<<br>Parameter<br>>" | Specifies the configuration parameter for the specified product or feature.                                                                                                                                                                                         |
| "<Value>"             | Specifies the value of the configuration parameter for the specified product or feature: <ul style="list-style-type: none"> <li>▪ One of these integers: 0, 1, 4</li> <li>▪ A string</li> </ul>                                                                     |
| dump                  | Creates a dump file of the Check Point Registry (\$CPDIR/registry/HKLM_registry.data) in the current working directory.<br>The name of the output file is RegDump.                                                                                                  |

## Notes

- On a Multi-Domain Server, you must run this command in the context of the relevant Domain Management Server.
- If you run the "cpprod\_util" command without parameters, it prints:
  - The list of all available products and features (for example, "FwIsFirewallMgmt", "FwIsLogServer", "FwIsStandAlone")
  - The type of the expected argument when you configure a product or feature ("no-parameter", "string-parameter", or "integer-parameter")
  - The type of the returned output ("status-output", or "no-output")
- To redirect the output of the "cpprod\_util" command, it is necessary to redirect the *stderr* to *stdout*:

```
cpprod_util <options> > <output file> 2>&1
```

Example:

```
cpprod_util > /tmp/output_of_cpprod_util.txt 2>&1
```

## Examples

### Example - Showing a list of all installed Check Point Products Packages on a Management Server

```
[Expert@MGMT:0]# cpprod_util CPPROD_GetInstalledProducts

```

**Example - Checking if this Security Gateway is a member of Full HA cluster**

```
[Expert@MyGW:0]# cprod_util FwIsFullHA
0
[Expert@MyGW:0]#
```

**Example - Checking if this Security Gateway is configured with Dynamically Assigned IP (DAIP)**

```
[Expert@MyGW:0]# cprod_util FwIsDAG
0
[Expert@MyGW:0]#
```

**Example - Checking if this Security Gateway is configured with IPv6 addresses**

```
[Expert@MyGW:0]# cprod_util FwIsFireWallIPv6
1
[Expert@MyGW:0]#
```

# cpsdwan

## Description

- Shows the current installed SD-WAN Policy on the Security Gateway.
- Fetches the SD-WAN Policy from a local directory on the Security Gateway.

For more information about SD-WAN, see [sk180605](#).

**Important** - You must run this command in the Expert mode.

## Syntax

- To show the built-in help:

```
cpsdwan help
```

- To show the current installed SD-WAN policy on the Security Gateway:

```
cpsdwan stat
```

- To fetch the SD-WAN policy stored locally on the Security Gateway in the default directory `$FWDIR/state/`:

```
cpsdwan fetch_local
```

- To fetch the SD-WAN policy stored locally on the Security Gateway in the specified directory:

```
cpsdwan fetch_new -d <Full Path to Directory> [-m {json | local}]
```

To uninstall the SD-WAN policy, see ["fw sdwan" on page 1258](#).

## Example

```
[Expert@MyGW:0]# fw sdwan stat
SDWAN Policy Status:
Policy Version: 121
SD-WAN Policy ID: 1670402027
SD-WAN Steering Policy ID: 7174322077137108993 (1)
Policy Installation Date and Time: 15/12/2023 15:34:03.882
[Expert@MyGW:0]#
```

# cpstart

## Description

Manually starts all Check Point processes and applications.

## Syntax on a Security Gateway / Cluster Member in Gaia Clish or the Expert mode

```
cpstart
```

## Syntax on a Scalable Platform Security Group in Gaia gClish

```
cpstart
```

## Syntax on a Scalable Platform Security Group in the Expert mode

```
g_all cpstart
```

## Log Files

- \$CPDIR/cpstart.log
- /opt/CPInstLog/cpstart\_error.log

# cpstat

## Description

Shows the status and statistics information for Check Point applications.

## Syntax on a Management Server in Gaia Clish or the Expert mode

```
cpstat [-d] [-h <Host>] [-p <Port>] [-s <SICName>] [-f <Flavor>]  
[-o <Polling Interval> [-c <Count>] [-e <Period>]] <Application  
Flag>
```

## Syntax on a Security Gateway / Cluster Member in Gaia Clish or the Expert mode

```
cpstat [-d] [-h <Host>] [-p <Port>] [-s <SICName>] [-f <Flavor>]  
[-o <Polling Interval> [-c <Count>] [-e <Period>]] <Application  
Flag>
```

## Syntax on a Scalable Platform Security Group in Gaia gClish

```
cpstat [-d] [-h <Host>] [-p <Port>] [-s <SICName>] [-f <Flavor>]  
[-o <Polling Interval> [-c <Count>] [-e <Period>]] <Application  
Flag>
```

## Syntax on a Scalable Platform Security Group in the Expert mode

```
g_all cpstat [-d] [-h <Host>] [-p <Port>] [-s <SICName>] [-f  
<Flavor>] [-o <Polling Interval> [-c <Count>] [-e <Period>]]  
<Application Flag>
```

**Note** - You can write the parameters in the syntax in any order.

## Parameters

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d           | <p>Runs the command in debug mode.<br/>Use only if you troubleshoot the command itself.</p> <p> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p> <p>The output shows the SNMP queries and SNMP responses for the applicable SNMP OIDs.</p>                                                                                                                                          |
| -h <Host>    | <p>Optional.<br/>When you run this command on a Management Server, this parameter specifies the managed Security Gateway / ClusterXL object.<br/>&lt;Host&gt; is an IPv4 address, a resolvable hostname, or a DAIP object name.<br/>The default is <code>localhost</code>.</p> <p> <b>Note</b> - On a Multi-Domain Server, you must run this command in the context of the applicable Domain Management Server:<code>mdsensv</code> <i>&lt;IP Address or Name of Domain Management Server&gt;</i>.</p> |
| -p <Port>    | <p>Optional.<br/>Port number of the Application Monitoring (AMON) server.<br/>The default port is 18192.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| -s <SICname> | <p>Optional.<br/>Secure Internal Communication (SIC) name of the Application Monitoring (AMON) server.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| -f <Flavor>  | <p>Optional.<br/>Specifies the type of the information to collect.<br/>If you do not specify a flavor explicitly, the command uses the first flavor in the <i>&lt;Application Flag&gt;</i>. To see all flavors, run the <code>cpstat</code> command without any parameters.</p>                                                                                                                                                                                                                                                                                                         |

| Parameter                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-o &lt;Polling Interval&gt;</code> | <p>Optional.</p> <p>Specifies the polling interval (in seconds) - how frequently the command collects and shows the information.</p> <p>Examples:</p> <ul style="list-style-type: none"> <li>▪ 0 - The command shows the results only once and the stops (this is the default value).</li> <li>▪ 5 - The command shows the results every 5 seconds in the loop.</li> <li>▪ 30 - The command shows the results every 30 seconds in the loop.</li> <li>▪ N - The command shows the results every N seconds in the loop.</li> </ul> <p>Use this parameter together with the "<code>-c &lt;Count&gt;</code>" parameter and the "<code>-e &lt;Period&gt;</code>" parameter.</p> <p>Example:</p> <pre>cpstat os -f perf -o 2</pre>                                                                                                 |
| <code>-c &lt;Count&gt;</code>            | <p>Optional.</p> <p>Specifies how many times the command runs and shows the results before it stops.</p> <p>You must use this parameter together with the "<code>-o &lt;Polling Interval&gt;</code>" parameter.</p> <p>Examples:</p> <ul style="list-style-type: none"> <li>▪ 0 - The command shows the results repeatedly every <code>&lt;Polling Interval&gt;</code> (this is the default value).</li> <li>▪ 10 - The command shows the results 10 times every <code>&lt;Polling Interval&gt;</code> and then stops.</li> <li>▪ 20 - The command shows the results 20 times every <code>&lt;Polling Interval&gt;</code> and then stops.</li> <li>▪ N - The command shows the results N times every <code>&lt;Polling Interval&gt;</code> and then stops.</li> </ul> <p>Example:</p> <pre>cpstat os -f perf -o 2 -c 2</pre> |

| Parameter                             | Description                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-e &lt;Period&gt;</code>        | <p>Optional.</p> <p>Specifies the time (in seconds), over which the command calculates the statistics.</p> <p>You must use this parameter together with the "<code>-o &lt;Polling Interval&gt;</code>" parameter.</p> <p>You can use this parameter together with the "<code>-c &lt;Count&gt;</code>" parameter.</p> <p>Example:</p> <pre>cpstat os -f perf -o 2 -c 2 -e 60</pre> |
| <code>&lt;Application Flag&gt;</code> | <p>Mandatory.</p> <p>See the table below with flavors for the application flags.</p>                                                                                                                                                                                                                                                                                              |

### These flavors are available for the application flags

 **Note** - The available flags depend on the enabled Software Blades. Some flags are supported only by a Security Gateway / ClusterXL, and some flags are supported only by a Management Server.

| Feature or Software Blade       | Flag   | Flavors                                                                                                                                                                                                                         |
|---------------------------------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

# cpstop

## Description

Manually stops all Check Point processes and applications.

## Syntax on a Security Gateway / Cluster Member in Gaia Clish or the Expert mode

```
cpstop [-fwflag {-default | -proc | -driver}]
```

## Syntax on a Scalable Platform Security Group in Gaia gClish

```
cpstop [-fwflag {-default | -proc | -driver}]
```

## Syntax on a Scalable Platform Security Group in the Expert mode

```
g_all cpstop [-fwflag {-default | -proc | -driver}]
```

## Parameters

-  **Important** - These parameters are for Check Point internal use. Do **not** use them, unless explicitly instructed by Check Point Support or R&D to do so.

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -fwflag -default | <ul style="list-style-type: none"> <li>Shuts down Check Point processes</li> <li>Loads the Default Filter policy (<code>defaultfilter</code>)</li> </ul>                                                                                                                                                                                                                                                              |
| -fwflag -proc    | <ul style="list-style-type: none"> <li>Shuts down Check Point processes</li> <li>Keeps the currently loaded kernel policy</li> <li>Maintains the Connections table, so that after you run the <i>"cpstart" on page 1032</i> command, you do not experience dropped packets because they are "out of state"</li> </ul> <p><b>Note</b> - Only security rules that do not use user space processes continue to work.</p> |
| -fwflag -driver  | <p>Unloads the Check Point kernel modules. Therefore, no policy is loaded.</p> <p> <b>Warning</b> - This leaves your Security Gateway, or aCluster Member without protection. Before you run this command, we recommend to disconnect your Security Gateway, or aCluster Member from the network completely.</p>                   |

# domains\_tool

## Description

When using Domain objects in the policy, you might want to know the IP addresses to which the Domain object is resolved on the Security Gateway (and kept in the cache). You might also want to know to which Domain objects a specific IP address is related.

Domains and IP addresses are mapped on the Security Gateway using Domains and cache tables. These tables contain information about the attachments between Domains used in the policy and their IP addresses.

This command shows the information about IP addresses and Domain objects. It also includes an option to see the Domains of an Updatable Object used in the policy.

For more information, see [sk161632](#).

### Important:

- You must run this command in the Expert mode.
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the Gaia Portal of the applicable Security Group.

## Syntax

```
domains_tool
  -d <Domain Name> [-m]
  -dx <Domain Name>
  -efo <Name of External Feed Object>
  -hc
  -ip <IP Address>
  -md <Domain Name 1> ... <Domain Name N>
  -o <Domain Name>
  -report
      [-extended]
      [-not_extended]
  -report ip <IP Address> [<Number of Hours>]
  -uo <Name of Updatable Object>
```

## Parameters

| Step                                                   | Instructions                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <pre>-report [{-not_ extended   - extended}]</pre>                 | <p>Runs a policy test and shows the report for Domain objects / Updatable Objects.<br/>The command asks you whether you wish to run an extended test.<br/>You can specify manually which test to run:</p> <ul style="list-style-type: none"> <li>■ domains_tool -report -not_extended<br/>Runs a regular test.</li> <li>■ domains_tool -report -extended<br/>Runs an extended test.</li> </ul> <p> <b>Warning</b> - The extended test runs the TCPdump tool for 60 seconds on all interfaces to capture the DNS traffic (port 53). This can create additional load on the CPU.</p> |
| <pre>-report ip &lt;IP Address&gt; [&lt;Number of Hours&gt;]</pre> | <p>Runs a test and shows the report for matching of the specified IP Address in the last specified number of hours (default is 2 hours).<br/>Example:<br/>domains_tool -report ip 192.168.3.57</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <pre>-uo &lt;Name of Updatable Object&gt;</pre>                    | <p>Shows a list of domains that the specified Updatable Object contains.<br/>This command shows only the domains of an Updatable Object when it is used in the policy.<br/>Example:<br/>domains_tool -uo "Dropbox Services"</p>                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Examples

### Example 1 - domains\_tool -d <Domain Name>

```
[Expert@MyGW:0]# domains_tool -d example.com
```

```
-----
| Given Domain name:  example.com  FQDN: yes
|
```

```
-----
| IPv4 addresses
```

```
| sub-domain |
```

```
-----
| 93.184.215.14
```

```
| no |
```

```
-----
Total of 1 IPv4 addresses found
```

```
-----
| Given Domain name:  example.com  FQDN: yes
|
```

```
-----
| IPv6 addresses
```

```
| sub-domain |
```

```
-----
| 2606:2800:21f:cb07:6820:80da:af6b:8b2c
```

```
| no |
```

```
-----
Total of 1 IPv6 addresses found
```

```
[Expert@MyGW:0]#
```

**Example 2 - domains\_tool -ip <IP Address>**

```
[Expert@MyGW:0]# domains_tool -ip 93.184.215.14
```

```
-----  
-----  
| Given IPv4 address: 93.184.215.14
```

```
|
```

```
-----  
-----  
| Domain name
```

```
| FQDN |
```

```
-----  
-----  
| www.example.com
```

```
| yes |
```

```
| example.com
```

```
| yes |
```

```
-----  
-----  
Total of 2 domains found
```

```
[Expert@MyGW:0]#
```

**Example 3 - domains\_tool -md <Domain Name 1> ... <Domain Name N>**

```
[Expert@MyGW:0]# domains_tool -md example1.com example2.com
{
  "ResponseCode" : 0,
  "ResponseItems" : [
    {
      "DomainName" : "example1.com",
      "IPs" : [
        {
          "IP" : "2606:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:7b2c",
          "IsSubDomain" : false
        },
        {
          "IP" : "xxx.xxx.xxx.14",
          "IsSubDomain" : false
        }
      ],
      "IsFQDN" : "yes",
      "NumOfIPs" : 2
    },
    {
      "DomainName" : "example2.com",
      "IPs" : [
        {
          "IP" : "2606:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:8c3d",
          "IsSubDomain" : false
        },
        {
          "IP" : "xxx.xxx.xxx.25",
          "IsSubDomain" : false
        }
      ],
      "IsFQDN" : "yes",
      "NumOfIPs" : 2
    }
  ]
}

[Expert@MyGW:0]#
```

**Example 4 - domains\_tool -o <Domain Name>**

```
[Expert@MyGW:0]# domains_tool -o example.com
```

```
-----  
-----  
| Given Domain Name: example.com
```

```
-----  
-----  
| Object Type      | Object Name
```

```
-----  
-----  
| Domain           | example.com
```

```
-----  
-----  
Total of 1 objects found
```

```
[Expert@MyGW:0]#
```

**Example 5 - domains\_tool -report**

```
[Expert@MyGW:0]# domains_tool -report
Would you like to run an extended test (for more information see
sk161632)? [y/n] n
Looking for domains in policy
```

```
Results:
No Domain or Updatable or Network Feed object in policy
[Expert@MyGW:0]#
```

```
[Expert@MyGW:0]# domains_tool -report
Would you like to run an extended test (for more information see
sk161632)? [y/n] y
Looking for domains in policy
Checking WSDNSD process is up and running
Checking whether DPL (DNS Passive Learning) is enabled
Trying to locate additional DNS servers (using tcpdump on DNS
traffic for 60 seconds)
```

```
Results:
No issues found
```

```
[Expert@MyGW:0]#
[Expert@MyGW:0]# domains_tool -hc
Health-Check status is OK
[Expert@MyGW:0]#
```

**Example 6 - domains\_tool -report ip <IP Address> [<Number of Hours>]**

```
[Expert@MyGW:0]# domains_tool -report ip 93.184.215.14

*****
* IP address: 93.184.215.14 *
* Timeframe: 2 hours      *
*****

Looking for policy objects associated with IP address
93.184.215.14
--> Found 1 objects

Looking for domains that were associated with IP address
93.184.215.14 but expired in the last 2 hours
--> Found 0 domains

Checking stability of DNS Passive Learning feature
--> Done

*** Analysis completed, report is available at /opt/CPsuite-
R82.10/fw1/log/domains_report_1732993728.txt ***

[Expert@MyGW:0]#
```

**Example 7 - domains\_tool -uo <Name of Updatable Object>**

```
[Expert@MyGW:0]# domains_tool -uo "Dropbox Services"

Domain tool looking for domains for 'Dropbox Services' and its
children objects:

Domains name list for 'Dropbox Services':

    [1] *.dropboxapi.com
    [2] dropboxapi.com
    ... ..
   [105] files-eu.dropbox.com

[Expert@MyGW:0]#
```

# dynamic\_objects

## Description

Manages dynamic objects and their applicable ranges of IP addresses on the Security Gateway / Cluster Members / Scalable Platform Security Group.

### Important:

- You can run this command only in the Expert mode.
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.

## Workflow

| Step | Instructions                                                                                                                                                                                                                                                                                                        |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1    | <p>In SmartConsole:</p> <ol style="list-style-type: none"> <li>1. Configure the applicable dynamic object.</li> <li>2. Install the Access Control Policy on the Security Gateway / ClusterXL object.</li> </ol>                                                                                                     |
| 2    | <p>On the Security Gateway / <i>each</i> Cluster Member / Security Group, run the "dynamic_objects" command to:</p> <ol style="list-style-type: none"> <li>1. Create the applicable dynamic object with the same name.</li> <li>2. Assign the applicable ranges of IP address to the new dynamic object.</li> </ol> |

## General syntax on a Security Gateway / Cluster Member in the Expert mode

```
dynamic_objects <Parameters>
```

## General syntax on a Scalable Platform Security Group in the Expert mode

```
g_all dynamic_objects <Parameters>
```

## Syntax for specific commands

- To show the built-in help:

```
dynamic_objects -h
```

- To show all configured dynamic objects and their ranges of IP addresses:

```
dynamic_objects -l
```

- To create a new dynamic object (and assign a range of IP addresses to it):

```
dynamic_objects -n <Object Name> [-r <FromIP1> <ToIP2> ...  
[<FromIPx> <ToIPy>] -a]
```

- To add a new a range of IP addresses to the specific existing dynamic object:

```
dynamic_objects -o <Object Name> -r <FromIP1> <ToIP2> ...  
[<FromIPx> <ToIPy>] -a
```

- To delete a range of IP addresses from the specific existing dynamic object:

```
dynamic_objects -o <Object Name> -r <FromIP1> <ToIP2> ...  
[<FromIPx> <ToIPy>] -d
```

- To update the specific existing dynamic object (and assign a different range of IP addresses to it):

```
dynamic_objects -u <Object Name> [-r <FromIP1> <ToIP2> ...  
[<FromIPx> <ToIPy>]]
```

- To compare the configured dynamic objects and objects configured in SmartConsole:

```
dynamic_objects -c
```

- To delete the specific existing dynamic object (and all ranges of IP addresses assigned to it):

```
dynamic_objects -do <Object Name>
```

- To delete all the existing dynamic objects (and all ranges of IP addresses assigned to them):

```
dynamic_objects -e
```

## Parameters

| Parameter                   | Description                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -h                          | Show the built-in help.                                                                                                                                                                                                                                                                                                                     |
| <Object Name>               | Specifies the name of the object: <ul style="list-style-type: none"> <li>■ As configured in SmartConsole</li> <li>■ As configured with the "dynamic_objects -n &lt;object name&gt;" command</li> </ul>                                                                                                                                      |
| -a                          | Adds the specified ranges of IP addresses to the specified dynamic object.                                                                                                                                                                                                                                                                  |
| -c                          | Compare all the dynamic objects between these two databases on the Security Cluster: <ul style="list-style-type: none"> <li>■ The local database with dynamic objects:<br/>\$FWDIR/database/dynamic_objects.db</li> <li>■ The local copy of the Management Server database with all relevant objects:<br/>\$FWDIR/conf/objects.C</li> </ul> |
| -cfo_show                   | Shows a list of IP addresses for all Generic Data Center (Custom Feed) objects.                                                                                                                                                                                                                                                             |
| -d                          | Deletes range of IP addresses from the specified dynamic object.                                                                                                                                                                                                                                                                            |
| -do <Name of Domain>        | Deletes the specified dynamic object (and all ranges of IP addresses assigned to it).                                                                                                                                                                                                                                                       |
| -e                          | Deletes all configured dynamic objects from the dynamic objects database (\$FWDIR/database/dynamic_objects.db).                                                                                                                                                                                                                             |
| -efo_show                   | Shows a list of IP addresses for all Network Feed objects. This parameter does not show Domains.                                                                                                                                                                                                                                            |
| -efo <Name of Network Feed> | Shows a list of Domains and IP ranges related to the specified Network Feed object.                                                                                                                                                                                                                                                         |

| Parameter                                                                                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <code>-o &lt;Object Name&gt;</code>                                                                               | Specifies the dynamic object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>-policy &lt;IP Address or Domain Name&gt;</code>                                                            | Shows all dynamically-updated objects used in the policy which are associated with the specified IP address or Domain name.                                                                                                                                                                                                                                                                                                                                                                            |
| <code>-r &lt;FromIP1&gt;</code><br><code>&lt;ToIP2&gt; ...</code><br><code>[&lt;FromIPx&gt; &lt;ToIPy&gt;]</code> | <p>Specifies the ranges of IP addresses in the format of pairs:</p> <div style="border: 1px solid black; padding: 5px; margin: 5px 0;"> <code>&lt;From_IP_Address&gt; &lt;To_IP_Address&gt;</code> </div> <p>For example, to specify two ranges, from 192.168.2.30 to 192.168.2.40 and from 192.168.2.50 to 192.168.2.60, enter these four IP addresses:</p> <div style="border: 1px solid black; padding: 5px; margin: 5px 0;"> <pre>192.168.2.30 192.168.2.40 192.168.2.50 192.168.2.60</pre> </div> |
| <code>-u &lt;Object Name&gt;</code>                                                                               | <p>Updates the specified dynamic object.</p> <p>If you specify a range of IP addresses, then the new range replaces all current ranges that are currently assigned to this dynamic object.</p>                                                                                                                                                                                                                                                                                                         |
| <code>-uo &lt;Object Name&gt;</code>                                                                              | Shows a list of IP addresses and Domains related to the specified Updatable object.                                                                                                                                                                                                                                                                                                                                                                                                                    |

**Example 1 - Create a new dynamic object named "bigserver" and assign to it the range of IP addresses 192.168.2.30-192.168.2.40**

Run either these two commands:

```
dynamic_objects -n bigserver
```

```
dynamic_objects -o bigserver -r 192.168.2.30 192.168.2.40 -a
```

Or this single command:

```
dynamic_objects -n bigserver -r 192.168.2.30 192.168.2.40 -a
```

**Example 2 - Update the ranges of IP addresses assigned to the dynamic object named "bigserver" from the current range to the new range 192.168.2.60-192.168.2.80**

```
dynamic_objects -u bigserver -r 192.168.2.60 192.168.2.80
```

# cpwd\_admin

## Description

The Check Point WatchDog (`cpwd`) is a process that invokes and monitors critical processes such as Check Point daemons on the local server, and attempts to restart them if they fail.

Among the processes monitored by Watchdog are `fwm`, `fwd`, `cpd`, `DAService`, and others.

The list of monitored processes depends on the installed and configured Check Point products and Software Blades.

The Check Point WatchDog writes monitoring information to the `$CPDIR/log/cpwd.elg` log file.

The `cpwd_admin` utility shows the status of the monitored processes, and configures the Check Point WatchDog.

## There are two types of Check Point WatchDog monitoring

| Monitoring | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Passive    | WatchDog restarts the process only when the process terminates abnormally.<br>In the output of the <code>cpwd_admin list</code> command, the <code>MON</code> column shows <code>N</code> for passively monitored processes.                                                                                                                                                                                                                               |
| Active     | WatchDog checks the process status every predefined interval.<br>WatchDog makes sure the process is alive, as well as properly functioning (not stuck on deadlocks, frozen, and so on).<br>In the output of the <code>cpwd_admin list</code> command, the <code>MON</code> column shows <code>Y</code> for actively monitored processes.<br>The list of actively monitored processes is predefined by Check Point.<br>Users cannot change or configure it. |

**Syntax on a Management Server in Gaia Clish or the Expert mode**

```
cpwd_admin
    config <options>
    del <options>
    detach <options>
    exist
    flist <options>
    getpid <options>
    kill
    list <options>
    monitor_list
    start <options>
    start_monitor
    stop <options>
    stop_monitor
```

**Syntax on a Security Gateway / Cluster Member in Gaia Clish or the Expert mode**

```
cpwd_admin
    config <options>
    del <options>
    detach <options>
    exist
    flist <options>
    getpid <options>
    kill
    list <options>
    monitor_list
    start <options>
    start_monitor
    stop <options>
    stop_monitor
```

Syntax on a Scalable Platform Security Group in Gaia gClish

```
cpwd_admin
  config <options>
  del <options>
  detach <options>
  exist
  flist <options>
  getpid <options>
  kill
  list <options>
  monitor_list
  start <options>
  start_monitor
  stop <options>
  stop_monitor
```

Syntax on a Scalable Platform Security Group in the Expert mode

```
g_all cpwd_admin
  config <options>
  del <options>
  detach <options>
  exist
  flist <options>
  getpid <options>
  kill
  list <options>
  monitor_list
  start <options>
  start_monitor
  stop <options>
  stop_monitor
```

Parameters

| Parameter           | Description                                                                                   |
|---------------------|-----------------------------------------------------------------------------------------------|
| config<br><options> | Configures the Check Point WatchDog.<br>See <a href="#">"cpwd_admin config" on page 224</a> . |

| Parameter           | Description                                                                                                                                                                                                                                                                                               |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| del<br><options>    | Temporarily deletes a monitored process from the WatchDog database of monitored processes.<br>See <a href="#">"cpwd_admin del" on page 229</a> .                                                                                                                                                          |
| detach<br><options> | Temporarily detaches a monitored process from the WatchDog monitoring.<br>See <a href="#">"cpwd_admin detach" on page 231</a> .                                                                                                                                                                           |
| exist               | Checks whether the WatchDog process cpwd is alive.<br>See <a href="#">"cpwd_admin exist" on page 233</a> .                                                                                                                                                                                                |
| flist<br><options>  | Saves the status of all monitored processes to a \$CPDIR/tmp/cpwd_list_<Epoch Timestamp>.lst file.<br>See <a href="#">"cpwd_admin flist" on page 234</a> .                                                                                                                                                |
| getpid<br><options> | Shows the PID of a monitored process.<br>See <a href="#">"cpwd_admin getpid" on page 236</a> .                                                                                                                                                                                                            |
| kill<br><options>   | Terminates the WatchDog process cpwd.<br>See <a href="#">"cpwd_admin kill" on page 237</a> .<br> <b>Important</b> - Do <b>not</b> run this command unless explicitly instructed by Check Point Support or R&D to do so. |
| list                | Prints the status of all monitored processes on the screen.<br>See <a href="#">"cpwd_admin list" on page 238</a> .                                                                                                                                                                                        |
| monitor_<br>list    | Prints the status of actively monitored processes on the screen.<br>See <a href="#">"cpwd_admin monitor_list" on page 243</a> .                                                                                                                                                                           |
| start<br><options>  | Starts a process as monitored by the WatchDog.<br>See <a href="#">"cpwd_admin start" on page 244</a> .                                                                                                                                                                                                    |
| start_<br>monitor   | Starts the active WatchDog monitoring - WatchDog monitors the predefined processes actively.<br>See <a href="#">"cpwd_admin start_monitor" on page 247</a> .                                                                                                                                              |
| stop<br><options>   | Stops a monitored process.<br>See <a href="#">"cpwd_admin stop" on page 248</a> .                                                                                                                                                                                                                         |
| stop_<br>monitor    | Stops the active WatchDog monitoring - WatchDog monitors all processes only passively.<br>See <a href="#">"cpwd_admin stop_monitor" on page 250</a> .                                                                                                                                                     |

## cpwd\_admin config

### Description

Configures the Check Point WatchDog.

-  **Important** - After changing the WatchDog configuration parameters, you must restart the WatchDog process with the "cpstop" and "cpstart" commands (which restart *all* Check Point processes).

**Syntax on a Management Server in Gaia Clish or the Expert mode**

```
cpwd_admin config
  -h
  -a <options>
  -d <options>
  -p
  -r
```

**Syntax on a Security Gateway / Cluster Member in Gaia Clish or the Expert mode**

```
cpwd_admin config
  -h
  -a <options>
  -d <options>
  -p
  -r
```

**Syntax on a Scalable Platform Security Group in Gaia gClish**

```
cpwd_admin config
  -h
  -a <options>
  -d <options>
  -p
  -r
```

**Syntax on a Scalable Platform Security Group in the Expert mode**

```
g_all cpwd_admin config
  -h
  -a <options>
  -d <options>
  -p
  -r
```

## Parameters

| Parameter                                                                                                                | Description                                                                                                                                                                                                                                                      |
|--------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -h                                                                                                                       | Shows built-in usage.                                                                                                                                                                                                                                            |
| -a <Configuration_Parameter_1>=<Value_1> <Configuration_Parameter_2>=<Value_2> ... <Configuration_Parameter_N>=<Value_N> | <p>Adds the WatchDog configuration parameters.</p> <p> <b>Note</b> - Spaces are not allowed between the name of the configuration parameter, the equal sign, and the value.</p> |
| -d <Configuration_Parameter_1> <Configuration_Parameter_2> ... <Configuration_Parameter_N>                               | Deletes the WatchDog configuration parameters that user added with the "cpwd_admin config -a" command.                                                                                                                                                           |
| -p                                                                                                                       | Shows the WatchDog configuration parameters that user added with the "cpwd_admin config -a" command.                                                                                                                                                             |
| -r                                                                                                                       | Restores the default WatchDog configuration.                                                                                                                                                                                                                     |

These are the available configuration parameters and the accepted values:

| Configuration Parameter | Accepted Values                                                              | Description                                                                                                                                                                                                                                                                                |
|-------------------------|------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| default_ctx             | Text string up to 128 characters                                             | On a VSX Gateway, configures the CTX value that is assigned to monitored processes, for which no CTX is specified.                                                                                                                                                                         |

| Configuration Parameter | Accepted Values                                                                        | Description                                                                                                                                                                                                                                                      |
|-------------------------|----------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| zero_timeout            | <ul style="list-style-type: none"> <li>Range: &gt; 0</li> <li>Default: 7200</li> </ul> | <p>After failing <code>no_limit</code> times to restart a process, the WatchDog waits <code>zero_timeout</code> seconds before it tries again.</p> <p>The value of the <code>zero_timeout</code> must be greater than the value of the <code>timeout</code>.</p> |

The WatchDog saves the user defined configuration parameters in the `$CPDIR/registry/HKLM_registry.data` file in the "`: (Wd_Config`" section:

```
("CheckPoint Repository Set"
 : (SOFTWARE
   : (CheckPoint
     : (CPshared
       :CurrentVersion (6.0)
       : (6.0
         ... ..
         : (reserved
           ... ..
           : (Wd
             : (Wd_Config
               :Configuration_Parameter_1 ("[4]Value_1"):Configuration_Parameter_2 ("
[4]Value_2")
             )
           )
         ... ..
```

## Example

```
[Expert@HostName:0]# cpwd_admin config -p
cpWatchDog doesn't have configuration parameters
[Expert@HostName:0]#
[Expert@HostName:0]# cpwd_admin config -a sleep_timeout=120 no_limit=12
[Expert@HostName:0]#
[Expert@HostName:0]# cpwd_admin config -p
cpWatchDog Configuration parameters are:
sleep_timeout : 120
no_limit : 12
[Expert@HostName:0]#
[Expert@HostName:0]# cpstop ; cpstart
[Expert@HostName:0]#

[Expert@HostName:0]# cpwd_admin config -r
cpWatchDog doesn't have configuration parameters
[Expert@HostName:0]#
[Expert@HostName:0]# cpstop ; cpstart
[Expert@HostName:0]#
[Expert@HostName:0]# cpwd_admin config -p
cpWatchDog doesn't have configuration parameters
[Expert@HostName:0]#
```

## Description

Configures the Check Point WatchDog.

 **Important** - After changing the WatchDog configuration parameters, you must restart the WatchDog process with the `cpstop` and `cpstart` commands (which restart *all* Check Point processes).

Syntax

```
cpwd_admin config
    -h
    -a <options>
    -d <options>
    -p
    -r
```

Parameters

| Parameter                                                                                                                | Description                                                                                                                                                         |
|--------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -h                                                                                                                       | Shows built-in usage.                                                                                                                                               |
| -a <Configuration_Parameter_1>=<Value_1> <Configuration_Parameter_2>=<Value_2> ... <Configuration_Parameter_N>=<Value_N> | Adds the WatchDog configuration parameters.<br><b>Note</b> - Spaces are not allowed between the name of the configuration parameter, the equal sign, and the value. |
| -d <Configuration_Parameter_1> <Configuration_Parameter_2> ... <Configuration_Parameter_N>                               | Deletes the WatchDog configuration parameters that user added with the <code>cpwd_admin config -a</code> command.                                                   |
| -p                                                                                                                       | Shows the WatchDog configuration parameters that user added with the <code>cpwd_admin config -a</code> command.                                                     |
| -r                                                                                                                       | Restores the default WatchDog configuration.                                                                                                                        |

These are the available configuration parameters and the accepted values:

| Configuration Parameter     | Accepted Values                                                                               | Description                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------|-----------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>default_ctx</code>    | Text string up to 128 characters                                                              | On a VSX Gateway, configures the CTX value that is assigned to monitored processes, for which no CTX is specified.                                                                                                                                                                                                                                                       |

| Configuration Parameter | Accepted Values                                                                        | Description                                                                                                                                                                                                  |
|-------------------------|----------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| sleep_timeout           | <ul style="list-style-type: none"> <li>Range: 0 - 3600</li> <li>Default: 60</li> </ul> | If rerun_mode=1, specifies how much time (in seconds) passes from a process failure until WatchDog tries to restart it.                                                                                      |
| stop_timeout            | <ul style="list-style-type: none"> <li>Range: &gt; 0</li> <li>Default: 60</li> </ul>   | Configures the time (in seconds) the WatchDog waits for a process stop command to complete.                                                                                                                  |
| zero_timeout            | <ul style="list-style-type: none"> <li>Range: &gt; 0</li> <li>Default: 7200</li> </ul> | <p>After failing no_limit times to restart a process, the WatchDog waits zero_timeout seconds before it tries again.</p> <p>The value of the zero_timeout must be greater than the value of the timeout.</p> |

The WatchDog saves the user defined configuration parameters in the \$CPDIR/registry/HKLM\_registry.data file in the ": (Wd\_Config" section:

```
("CheckPoint Repository Set"
: (SOFTWARE
: (CheckPoint
: (CPshared
: CurrentVersion (6.0)
: (6.0
... ..
: (reserved
... ..
: (Wd
: (Wd_Config
: Configuration_Parameter_1 ("[4]Value_1")
: Configuration_Parameter_2 ("[4]Value_2")
)
)
... ..
```

## Example

```
[Expert@HostName:0]# cpwd_admin config -p
cpWatchDog doesn't have configuration parameters
[Expert@HostName:0]#
[Expert@HostName:0]# cpwd_admin config -a sleep_timeout=120 no_limit=12
[Expert@HostName:0]#
[Expert@HostName:0]# cpwd_admin config -p
cpWatchDog Configuration parameters are:
sleep_timeout : 120
no_limit : 12
[Expert@HostName:0]#
[Expert@HostName:0]# cpstop ; cpstart
[Expert@HostName:0]#

[Expert@HostName:0]# cpwd_admin config -r
cpWatchDog doesn't have configuration parameters
[Expert@HostName:0]#
[Expert@HostName:0]# cpstop ; cpstart
[Expert@HostName:0]#
[Expert@HostName:0]# cpwd_admin config -p
cpWatchDog doesn't have configuration parameters
[Expert@HostName:0]#
```

# cpwd\_admin del

## Description

Temporarily deletes a monitored process from the WatchDog database of monitored processes.

### Notes:

- WatchDog stops monitoring the detached process, but the process stays alive.
- The "[cpwd\\_admin list](#)" on [page 238](#) command does not show the deleted process anymore.
- This change applies until all Check Point services restart during boot, or with the "[cpstart](#)" on [page 208](#) command.

## Syntax on a Management Server in Gaia Clish or the Expert mode

```
cpwd_admin del -name <Application Name>
```

## Syntax on a Security Gateway / Cluster Member in Gaia Clish or the Expert mode

```
cpwd_admin del -name <Application Name> [-ctx <VSID>]
```

## Syntax on a Scalable Platform Security Group in Gaia gClish

```
cpwd_admin del -name <Application Name> [-ctx <VSID>]
```

## Syntax on a Scalable Platform Security Group in the Expert mode

```
g_all cpwd_admin del -name <Application Name> [-ctx <VSID>]
```

## Parameters

| Parameter                             | Description                                                                                                                                                                                                                                                              |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;Application Name&gt;</code> | Name of the monitored Check Point process as you see in the output of the <a href="#">"cpwd_admin list" on page 238</a> command in the leftmost column APP.<br>Examples: <ul style="list-style-type: none"><li>■ FWM</li><li>■ FWD</li><li>■ CPD</li><li>■ CPM</li></ul> |
| <code>-ctx &lt;VSID&gt;</code>        | On a VSX Gateway, specifies the context of the applicable Virtual System.                                                                                                                                                                                                |

## Example

```
[Expert@HostName:0]# cpwd_admin del -name FWD
cpwd_admin:
successful Del operation
[Expert@HostName:0]#
```

# cpwd\_admin detach

## Description

Temporarily detaches a monitored process from the WatchDog monitoring.

### Notes:

- WatchDog stops monitoring the detached process, but the process stays alive.
- The "[cpwd\\_admin list](#)" on [page 238](#) command does not show the detached process anymore.
- This change applies until all Check Point services restart during boot, or with the "[cpstart](#)" on [page 208](#) command.

## Syntax on a Management Server in Gaia Clish or the Expert mode

```
cpwd_admin detach -name <Application Name>
```

## Syntax on a Security Gateway / Cluster Member in Gaia Clish or the Expert mode

```
cpwd_admin detach -name <Application Name> [-ctx <VSID>]
```

## Syntax on a Scalable Platform Security Group in Gaia gClish

```
cpwd_admin detach -name <Application Name> [-ctx <VSID>]
```

## Syntax on a Scalable Platform Security Group in the Expert mode

```
g_all cpwd_admin detach -name <Application Name> [-ctx <VSID>]
```

## Parameters

|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;Application Name&gt;</code> | <p>Name of the monitored Check Point process as you see in the output of the <a href="#">"cpwd_admin list" on page 238</a> command in the leftmost column APP.</p> <p>Examples:</p> <ul style="list-style-type: none"><li>■ FWM</li><li>■ FWD</li><li>■ CPD</li><li>■ CPM</li></ul> |
| <code>-ctx &lt;VSID&gt;</code>        | <p>On a VSX Gateway, specifies the context of the applicable Virtual System.</p>                                                                                                                                                                                                    |

## Example

```
[Expert@HostName:0]# cpwd_admin detach -name FWD
cpwd_admin:
successful Detach operation
[Expert@HostName:0]#
```

# cpwd\_admin exist

## Description

Checks whether the WatchDog process `cpwd` is alive.

## Syntax on a Management Server in Gaia Clish or the Expert mode

```
cpwd_admin exist
```

## Syntax on a Security Gateway / Cluster Member in Gaia Clish or the Expert mode

```
cpwd_admin exist
```

## Syntax on a Scalable Platform Security Group in Gaia gClish

```
cpwd_admin exist
```

## Syntax on a Scalable Platform Security Group in the Expert mode

```
g_all cpwd_admin exist
```

## Example

```
[Expert@HostName:0]# cpwd_admin exist  
cpwd_admin: cpWatchDog is running  
[Expert@HostName:0]#
```

# cpwd\_admin flist

## Description

Saves the status of all WatchDog monitored processes to a file.

## Syntax on a Management Server in Gaia Clish or the Expert mode

```
cpwd_admin flist [-full]
```

## Syntax on a Security Gateway / Cluster Member in Gaia Clish or the Expert mode

```
cpwd_admin flist [-full] [-ctx <VSID>]
```

## Syntax on a Scalable Platform Security Group in Gaia gClish

```
cpwd_admin flist [-full] [-ctx <VSID>]
```

## Syntax on a Scalable Platform Security Group in the Expert mode

```
g_all cpwd_admin flist [-full] [-ctx <VSID>]
```

## Parameters

| Parameter   | Description                                                               |
|-------------|---------------------------------------------------------------------------|
| -full       | Shows the verbose output.                                                 |
| -ctx <VSID> | On a VSX Gateway, specifies the context of the applicable Virtual System. |

## Output

| Column     | Description                                                                                                                                                                                                                       |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| APP        | Shows the WatchDog name of the monitored process.                                                                                                                                                                                 |
| CTX        | On a VSX Gateway, shows the VSID, in which the monitored process runs.                                                                                                                                                            |
| PID        | Shows the PID of the monitored process.                                                                                                                                                                                           |
| STAT       | Shows the status of the monitored process: <ul style="list-style-type: none"> <li>▪ E - executing</li> <li>▪ T - terminated</li> </ul>                                                                                            |
| #START     | Shows how many times the WatchDog started the monitored process.                                                                                                                                                                  |
| START_TIME | Shows the time when the WatchDog started the monitored process for the last time.                                                                                                                                                 |
| SLP/LIMIT  | In verbose output, shows the values of the <code>sleep_timeout</code> and <code>no_limit</code> configuration parameters (see <a href="#">"cpwd_admin config" on page 224</a> ).                                                  |
| MON        | Shows how the WatchDog monitors this process (see the explanation for the <a href="#">"cpwd_admin" on page 220</a> ): <ul style="list-style-type: none"> <li>▪ Y - Active monitoring</li> <li>▪ N - Passive monitoring</li> </ul> |
| COMMAND    | Shows the command the WatchDog run to start this process.                                                                                                                                                                         |

## Example

```
[Expert@HostName:0]# cpwd_admin flist
/opt/CPshrd-R82.10/tmp/cpwd_list_1564617600.lst
[Expert@HostName:0]#
```

# cpwd\_admin getpid

## Description

Shows the PID of a WatchDog monitored process.

## Syntax on a Management Server in Gaia Clish or the Expert mode

```
cpwd_admin getpid -name <Application Name>
```

## Syntax on a Security Gateway / Cluster Member in Gaia Clish or the Expert mode

```
cpwd_admin getpid -name <Application Name> [-ctx <VSID>]
```

## Syntax on a Scalable Platform Security Group in Gaia gClish

```
cpwd_admin getpid -name <Application Name> [-ctx <VSID>]
```

## Syntax on a Scalable Platform Security Group in the Expert mode

```
g_all cpwd_admin getpid -name <Application Name> [-ctx <VSID>]
```

## Parameters

| Parameter          | Description                                                                                                                                                                                                                                                                |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <Application Name> | Name of the monitored Check Point process as you see in the output of the " <a href="#">cpwd_admin list</a> " on page 238 command in the leftmost column APP.<br>Examples: <ul style="list-style-type: none"><li>■ FWM</li><li>■ FWD</li><li>■ CPD</li><li>■ CPM</li></ul> |
| -ctx <VSID>        | On VSX Gateway, specifies the context of the applicable Virtual System.                                                                                                                                                                                                    |

## Example

```
[Expert@HostName:0]# cpwd_admin getpid -name FWD
5640
[Expert@HostName:0]#
```

# cpwd\_admin kill

## Description

Terminates the WatchDog process `cpwd`.

**Important** - Do **not** run this command unless explicitly instructed by Check Point Support or R&D to do so.

To restart the WatchDog process, you must restart all Check Point services with the *"cpstop" on page 219* and *"cpstart" on page 208* commands.

## Syntax on a Management Server in Gaia Clish or the Expert mode

```
cpwd_admin kill
```

## Syntax on a Security Gateway / Cluster Member in Gaia Clish or the Expert mode

```
cpwd_admin kill
```

## Syntax on a Scalable Platform Security Group in Gaia gClish

```
cpwd_admin kill
```

## Syntax on a Scalable Platform Security Group in the Expert mode

```
g_all cpwd_admin kill
```

# cpwd\_admin list

## Description

Prints the status of all WatchDog monitored processes on the screen.

**Note** - By default, WatchDog monitors a maximum of 10000 processes.

To increase this threshold, use the command "cpwd\_admin config -a num\_of\_procs=<value>".

See "[cpwd\\_admin config](#)" on page 224.

## Syntax on a Management Server in Gaia Clish or the Expert mode

```
cpwd_admin list [-full]
```

## Syntax on a Security Gateway / Cluster Member in Gaia Clish or the Expert mode

```
cpwd_admin list [-full] [-ctx <VSID>]
```

## Syntax on a Scalable Platform Security Group in Gaia gClish

```
cpwd_admin list [-full] [-ctx <VSID>]
```

## Syntax on a Scalable Platform Security Group in the Expert mode

```
g_all cpwd_admin list [-full] [-ctx <VSID>]
```

## Parameters

| Parameter   | Description                                                               |
|-------------|---------------------------------------------------------------------------|
| -full       | Shows the verbose output.                                                 |
| -ctx <VSID> | On a VSX Gateway, specifies the context of the applicable Virtual System. |

## Output

| Column     | Description                                                                                                                                                                                                                       |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| APP        | Shows the WatchDog name of the monitored process.                                                                                                                                                                                 |
| CTX        | On a VSX Gateway, shows the VSID, in which the monitored process runs.                                                                                                                                                            |
| PID        | Shows the PID of the monitored process.                                                                                                                                                                                           |
| STAT       | Shows the status of the monitored process: <ul style="list-style-type: none"> <li>▪ E - executing</li> <li>▪ T - terminated</li> </ul>                                                                                            |
| #START     | Shows how many times the WatchDog started the monitored process.                                                                                                                                                                  |
| START_TIME | Shows the time when the WatchDog started the monitored process for the last time.                                                                                                                                                 |
| SLP/LIMIT  | In verbose output, shows the values of the <code>sleep_timeout</code> and <code>no_limit</code> configuration parameters (see <a href="#">"cpwd_admin config" on page 224</a> ).                                                  |
| MON        | Shows how the WatchDog monitors this process (see the explanation for the <a href="#">"cpwd_admin" on page 220</a> ): <ul style="list-style-type: none"> <li>▪ Y - Active monitoring</li> <li>▪ N - Passive monitoring</li> </ul> |
| COMMAND    | Shows the command the WatchDog run to start this process.                                                                                                                                                                         |

## Examples

### Example - Default output on a Management Server

```

# cpwd\_admin monitor\_list

## Description

Prints the status of actively monitored processes on the screen.

See the explanation about the active monitoring in ["cpwd\\_admin" on page 220](#).

## Syntax on a Management Server in Gaia Clish or the Expert mode

```
cpwd_admin monitor_list
```

## Syntax on a Security Gateway / Cluster Member in Gaia Clish or the Expert mode

```
cpwd_admin monitor_list
```

## Syntax on a Scalable Platform Security Group in Gaia gClish

```
cpwd_admin monitor_list
```

## Syntax on a Scalable Platform Security Group in the Expert mode

```
g_all cpwd_admin monitor_list
```

## Example

```
[Expert@HostName:0]# cpwd_admin monitor_list
cpwd_admin:
APP      FILE_NAME                NO_MSG_TIMES  LAST_MSG_TIME
CPD      CPD_5420_4714.mntr           0/10          [19:00:33] 31/5/2019
[Expert@HostName:0]#
```

# cpwd\_admin start

## Description

Starts a process as monitored by the WatchDog.

## Syntax on a Management Server in Gaia Clish or the Expert mode

```
cpwd_admin start -name <Application Name> -path "<Full Path to Executable>" -command "<Command Syntax>" [-env {inherit | <Env_Var>=<Value>} [-slp_timeout <Timeout>] [-retry_limit {<Limit> | u}]
```

## Syntax on a Security Gateway / Cluster Member in Gaia Clish or the Expert mode

```
cpwd_admin start -name <Application Name> [-ctx <VSID>] -path "<Full Path to Executable>" -command "<Command Syntax>" [-env {inherit | <Env_Var>=<Value>} [-slp_timeout <Timeout>] [-retry_limit {<Limit> | u}]
```

## Syntax on a Scalable Platform Security Group in Gaia gClish

```
cpwd_admin start -name <Application Name> [-ctx <VSID>] -path "<Full Path to Executable>" -command "<Command Syntax>" [-env {inherit | <Env_Var>=<Value>} [-slp_timeout <Timeout>] [-retry_limit {<Limit> | u}]
```

## Syntax on a Scalable Platform Security Group in the Expert mode

```
g_all cpwd_admin start -name <Application Name> [-ctx <VSID>] -path "<Full Path to Executable>" -command "<Command Syntax>" [-env {inherit | <Env_Var>=<Value>} [-slp_timeout <Timeout>] [-retry_limit {<Limit> | u}]
```

## Parameters

## Example

For the list of process and the applicable syntax, see [sk97638](#).

# cpwd\_admin start\_monitor

## Description

Starts the active WatchDog monitoring. WatchDog monitors the predefined processes actively.

See the explanation for the ["cpwd\\_admin" on page 220](#) command.

## Syntax on a Management Server in Gaia Clish or the Expert mode

```
cpwd_admin start_monitor
```

## Syntax on a Security Gateway / Cluster Member in Gaia Clish or the Expert mode

```
cpwd_admin start_monitor
```

## Syntax on a Scalable Platform Security Group in Gaia gClish

```
cpwd_admin start_monitor
```

## Syntax on a Scalable Platform Security Group in the Expert mode

```
g_all cpwd_admin start_monitor
```

## Example

```
[Expert@HostName:0]# cpwd_admin start_monitor
cpwd_admin:
CPWD has started to perform active monitoring on Check Point services/processes
[Expert@HostName:0]#
```

# cpwd\_admin stop

## Description

Stops a WatchDog monitored process.

**Important** - This change does **not** survive reboot.

## Syntax on a Management Server in Gaia Clish or the Expert mode

```
cpwd_admin stop -name <Application Name> [-path "<Full Path to Executable>" -command "<Command Syntax>" [-env {inherit | <Env_Var>=<Value>}]
```

## Syntax on a Security Gateway / Cluster Member in Gaia Clish or the Expert mode

```
cpwd_admin stop -name <Application Name> [-ctx <VSID>] [-path "<Full Path to Executable>" -command "<Command Syntax>" [-env {inherit | <Env_Var>=<Value>}]
```

## Syntax on a Scalable Platform Security Group in Gaia gClish

```
cpwd_admin stop -name <Application Name> [-ctx <VSID>] [-path "<Full Path to Executable>" -command "<Command Syntax>" [-env {inherit | <Env_Var>=<Value>}]
```

## Syntax on a Scalable Platform Security Group in the Expert mode

```
g_all cpwd_admin stop -name <Application Name> [-ctx <VSID>] [-path "<Full Path to Executable>" -command "<Command Syntax>" [-env {inherit | <Env_Var>=<Value>}]
```

## Parameters

| Parameter                                                   | Description                                                                                                                                                                                                                                                                                                                                                                   |

Must enclose in double quotes.</p> <p>Examples:</p> <ul style="list-style-type: none"> <li>■ For FWM: "\$FWDIR/bin/fwm"</li> <li>■ For FWD: "/opt/CPsuite-R82.10/fw1/bin/fw"</li> <li>■ For CPD: "\$CPDIR/bin/cpd_admin"</li> </ul>                     |
| <code>-command "&lt;Command Syntax&gt;"</code>              | <p>The command and its arguments to run. Must enclose in double quotes.</p> <p>Examples:</p> <ul style="list-style-type: none"> <li>■ For FWM: "fw kill fwm"</li> <li>■ For FWD: "fw kill fwd"</li> <li>■ For CPD: "cpd_admin stop"</li> </ul>                                                                                                                                |
| <code>-env {inherit   &lt;Env_Var&gt;=&lt;Value&gt;}</code> | <p>Configures whether to inherit the environment variables from the shell.</p> <ul style="list-style-type: none"> <li>■ <code>inherit</code> - Inherits all the environment variables (WatchDog supports up to 80 environment variables)</li> <li>■ <code>&lt;Env_Var&gt;=&lt;Value&gt;</code> - Assigns the specified value to the specified environment variable</li> </ul> |

## Example

For the list of process and the applicable syntax, see [sk97638](#).

# cpwd\_admin stop\_monitor

## Description

Stops the active WatchDog monitoring. WatchDog monitors all processes only passively.

See the explanation for the ["cpwd\\_admin" on page 220](#) command.

## Syntax on a Management Server in Gaia Clish or the Expert mode

```
cpwd_admin stop_monitor
```

## Syntax on a Security Gateway / Cluster Member in Gaia Clish or the Expert mode

```
cpwd_admin stop_monitor
```

## Syntax on a Scalable Platform Security Group in Gaia gClish

```
cpwd_admin stop_monitor
```

## Syntax on a Scalable Platform Security Group in the Expert mode

```
g_all cpwd_admin stop_monitor
```

## Example

```
[Expert@HostName:0]# cpwd_admin stop_monitor
cpwd_admin:
CPWD has stopped performing active monitoring on Check Point services/processes
[Expert@HostName:0]#
```

**fw**

## Description

- Fetches and unloads Threat Prevention policy.
- Shows CGNAT (Carrier-Grade NAT) information.
- Controls the Firewall module.
- Generates the Default Filter policy files.
- Fetches the policy from the Management Server, peer Cluster Member, or local directory.
- Fetches the specified Security or Audit log files from the specified Check Point server.
- Shows the list of interfaces and their IP addresses.
- Shows information about Check Point servers in High Availability configuration and their states.
- Controls ISP links in ISP Redundancy configuration.
- Kills the specified Check Point processes.
- Shows a list of hosts protected by the Security Gateway.
- Shows the content of Check Point log files.
- Switches the current active log file.
- Shows a list of Security or Audit log files.
- Merges several input log files into a single log file.
- Runs FW Monitor to capture the traffic that passes through the Security Gateway.
- Rebuilds pointer files for Security or Audit log files.
- Manages the Suspicious Activity Monitoring (SAM) rules.
- Manages the Suspicious Activity Policy editor.
- Shows the contents of the Unified Policy kernel tables.
- Fetches the SD-WAN policy from a local directory.
- Shows the currently installed policy.
- Shows and deletes the contents of the specified kernel tables.
- Executes the offline Unified Policy.
- Removes all policies from the Security Gateway or Cluster Member.
- Shows the Security Gateway major and minor version number and build number.

 **Important:**

- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.

**Syntax**

```
fw [-d] [-i]
    amw <options>
    cgnat <options>
    ctl <options>
    defaultgen
    fetch <options>
    fetchlogs <options>
    getifs
    hastat <options>
    isp_link <options>
    kill <options>
    lichosts <options>
    log <options>
    logswitch <options>
    lslogs <options>
    mergefiles <options>
    repairlog <options>
    sam <options>
    sam_policy <options>
    sdwan <options>
    showuptables <options>
    stat
    tab <options>
    unloadlocal
    up_execute <options>
    ver <options>
```

## Parameters

| Parameter              | Description                                                                                                                                                                                                                                                                              |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d                     | <p>Runs the command in debug mode.<br/>Use only if you troubleshoot the command itself.</p> <p>★ <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p>                     |
| -i                     | <p>Specifies the CoreXL Firewall instance.<br/>See <a href="#">"fw -i" on page 1098</a>.</p>                                                                                                                                                                                             |

| <code>unloadlocal</code>                                  | Uninstalls all policies from the Security Gateway or Cluster Member.<br>See <a href="#">"fw unloadlocal" on page 1279</a> . |
| <code>up_execute</code><br><code>&lt;options&gt;</code>   | Executes the offline Unified Policy.<br>See <a href="#">"fw up_execute" on page 1284</a> .                                  |
| <code>ver &lt;options&gt;</code>                          | Shows the Security Gateway major and minor version number and build number.<br>See <a href="#">"fw ver" on page 1296</a> .  |

# fw -i

## Description

By default, the *"fw" on page 1092* commands apply to the entire Security Gateway. The fw commands show aggregated information for all CoreXL Firewall instances. The fw -i commands apply to the specified CoreXL Firewall instance.

-  **Important:**
- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
  - In a Cluster, you must configure all the Cluster Members in the same way.
  - On Scalable Platforms, you must connect to the applicable Security Group.

## Syntax

```
fw -i <ID of CoreXL Firewall instance> <Command>
```

## Parameters

| Parameter                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ID of CoreXL Firewall instance> | Specifies the ID of the CoreXL Firewall instance.<br>To see the available IDs, run the <i>"fw ctl multik stat" on page 1750</i> command.                                                                                                                                                                                                                                                                                                                                                                       |
| <Command>                        | <div>Only these commands support the fw -i syntax:<ul style="list-style-type: none"><li>■ fw -i &lt;ID&gt; conntab ...</li><li>■ fw -i &lt;ID&gt; ctl get ...</li><li>■ fw -i &lt;ID&gt; ctl leak ...</li><li>■ fw -i &lt;ID&gt; ctl pstat ...</li><li>■ fw -i &lt;ID&gt; ctl set ...</li><li>■ fw -i &lt;ID&gt; monitor ...</li><li>■ fw -i &lt;ID&gt; tab ...</li></ul></div> <div>For details and additional parameters for any of these commands, refer to the corresponding entry for each command.</div> |

## Example 1 - Show the Connections table for CoreXL Firewall instance #1

```
fw -i 1 tab -t connections
```

## Example 2 - Show various internal statistics for CoreXL Firewall instance #1

```
fw -i 1 ctl pstat
```

## fw amw

### Description

Fetches and unloads Threat Prevention policy.

Threat Prevention policy applies to these Software Blades:

- Anti-Bot
- Anti-Spam
- Anti-Virus
- IPS
- Threat Emulation
- Threat Extraction

### Important:

- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.

## Syntax

- To fetch the Threat Prevention policy from the Management Server:

```
fw [-d] amw fetch -f [-i] [-n] [-r]
```

- To fetch the Threat Prevention policy from a peer Cluster Member, and, if it fails, then from the Management Server:

```
fw [-d] amw fetch -f -c [-i] [-n] [-r]
```

- To fetch the Threat Prevention policy from the specified Check Point server(s):

```
fw [-d] amw fetch [-i] [-n] [-r] <Master 1> [<Master 2> ...]
```

- To fetch the Threat Prevention policy stored locally on the Security Gateway:

```
fw [-d] amw fetch local [-nu]
```

```
fw [-d] amw fetch localhost [-nu]
```

- To fetch the Threat Prevention policy stored locally on the Security Gateway in the specified directory:

```
fw [-d] amw fetchlocal [-lu] -d <Full Path to Directory>
```

- To unload the current Threat Prevention policy:

```
fw [-d] amw unload
```

## Parameters

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| fw -d amw<br>... | Runs the command in debug mode.<br>Use only if you troubleshoot the command itself.<br> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session. |
| fw amw<br>fetch  | Fetches the Threat Prevention policy from the specified Check Point server(s).<br>These can be a Management Server, or a peer Cluster Member.                                                                                                                                                                                              |

| Parameter                                             | Description                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| fw amw<br>fetch local<br>fw amw<br>fetch<br>localhost | Fetches the Threat Prevention policy that is stored locally on the Security Gateway in the <code>\$FWDIR/state/local/AMW/</code> directory.                                                                                                                                                                                                                                     |
| fw amw<br>fetchlocal                                  | Fetches the Threat Prevention policy that stored locally on the Security Gateway in the specified directory.                                                                                                                                                                                                                                                                    |
| fw amw<br>unload                                      | Unloads the current Threat Prevention policy from the Security Gateway.<br> <b>Important</b> - This significantly decreases the security on the Security Gateway. This is the same as if you disable the Threat Prevention Software Blades on the Security Gateway.                            |
| -c                                                    | Specifies that you fetch the policy from a peer Cluster Member.<br> <b>Notes:</b> <ul style="list-style-type: none"> <li>▪ Must also use the "-f" parameter.</li> <li>▪ Works only in cluster.</li> </ul>                                                                                      |
| -f                                                    | Specifies that you fetch the policy from a Management Server listed in the <code>\$FWDIR/conf/masters</code> file.                                                                                                                                                                                                                                                              |
| -i                                                    | On a Security Gateway with dynamically assigned IP address (DAIP), specifies to ignore the SIC name and object name.                                                                                                                                                                                                                                                            |
| -lu                                                   | Specifies to perform a late update - to load signatures just after the Security Gateway copies the policy files to the local directory <code>\$FWDIR/state/local/AMW/</code> .                                                                                                                                                                                                  |
| -n                                                    | Specifies not to load the fetched policy, if it is the same as the policy already located on the Security Gateway.                                                                                                                                                                                                                                                              |
| -nu                                                   | Specifies not to update the currently installed policy.                                                                                                                                                                                                                                                                                                                         |
| -r                                                    | On a Cluster Member, specifies to ignore this option in SmartConsole <b>Install Policy</b> window:<br><b>For gateway clusters, if installation on a cluster member fails, do not install on that cluster</b><br> <b>Best Practice</b> - Use this parameter if a peer Cluster Member is Down. |

| Parameter                                                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;Master 1&gt;</code><br><code>[&lt;Master 2&gt;</code><br><code>...]</code> | <p>Specifies the Check Point server(s), from which to fetch the Threat Prevention policy.</p> <p>You can fetch the Threat Prevention policy from the Management Server, or a peer Cluster Member.</p> <p> <b>Notes:</b></p> <ul style="list-style-type: none"> <li>■ If you fetch the Threat Prevention policy from the Management Server, you can enter one of these: <ul style="list-style-type: none"> <li>• The main IP address of the Management Server object.</li> <li>• The object name of the Management Server.</li> <li>• The hostname that the Security Gateway resolves to the main IP address of the Management Server.</li> </ul> </li> <li>■ If you fetch the Threat Prevention policy from a peer Cluster Member, you can enter one of these: <ul style="list-style-type: none"> <li>• The main IP address of the Cluster Member object.</li> <li>• The IP address of the Sync interface on the Cluster Member.</li> </ul> </li> <li>■ If the fetch from the first specified <code>&lt;Master&gt;</code> fails, the Security Gateway fetches the policy from the second specified <code>&lt;Master&gt;</code>, and so on. | <code>-d &lt;Full Path to Directory&gt;</code>                                       | <p>Specifies local directory on the Security Gateway, from which to fetch the Threat Prevention policy files.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Example

```
[Expert@MyGW:0]# fw amw fetch local
Installing Threat Prevention policy from local
Fetching Threat Prevention policy succeeded
[Expert@MyGW:0]#
```

# fw cgnat

## Description

Shows CGNAT (Carrier-Grade NAT) information about Dynamic NAT port allocation. See [sk120296](#).

 **Important** - You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).

## Syntax

```
fw [-d] cgnat
    clean
    info [-s]
    origin <IP Address>
    translated <IP Address>
```

## Parameters

| Parameter                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Example

```
fw cgnat info -s
```

# fw ctl

## Description

Controls the Firewall kernel module.

### Important:

- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.

## Syntax

```
fw [-d] ctl
    arp <options>
    bench <options>
    block <options>
    chain
    conn
    conntab <options>
    cpasstat <options>
    debug <options>
    get <options>
    iflist
    install
    kdebug <options>
    pstat <options>
    set <options>
    tcpstrstat <options>
    uninstall
```

## Parameters

| Parameter | Description                                                                                                                                                                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d        | <p>Runs the command in debug mode.<br/>Use only if you troubleshoot the command itself.</p> <p>★ <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p> |

| Parameter             | Description                                                                                                                                                                                                                                                                                                   |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| arp<br><options>      | Shows the configured Proxy ARP entries based on the \$FWDIR/conf/local.arp file on the Security Gateway.<br>See <a href="#">"fw ctl arp" on page 1109</a> .                                                                                                                                                   |

| leak<br><options>       | Generates leak detection report.<br>See <a href="#">"fw ctl leak" on page 1138</a> .                                                                              |
| pstat<br><options>      | Shows Security Gateway various internal statistics.<br>See <a href="#">"fw ctl pstat" on page 1142</a> .                                                          |
| set<br><options>        | Configures the specified value for the specified kernel parameter.<br>See <a href="#">"fw ctl set" on page 1145</a> .                                             |
| tcpstrstat<br><options> | Generates statistics report about TCP Streaming.<br>See <a href="#">"fw ctl tcpstrstat" on page 1149</a> .                                                        |
| uninstall               | Tells the operating system to stop passing packets to Firewall, and unloads the current Security Policy.<br>See <a href="#">"fw ctl uninstall" on page 1151</a> . |

## fw ctl arp

### Description

Shows the configured Proxy ARP entries based on the `$FWDIR/conf/local.arp` file on the Security Gateway.

For more information about the Proxy ARP, see [sk30197](#).

#### Important:

- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- On Scalable Platforms, you must connect to the applicable Security Group.

### Syntax

```
fw [-d] ctl arp
    [-h]
    [-n]
```

### Parameters

| Parameter | Description                                                                                                                                                                                                                                                                                                                                |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d        | Runs the command in debug mode.<br>Use only if you troubleshoot the command itself.<br> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session. |
| -h        | Shows the built-in help.                                                                                                                                                                                                                                                                                                                   |
| -n        | Specifies not to resolve hostnames.                                                                                                                                                                                                                                                                                                        |

## fw ctl bench

### Description

The benchmark mechanism provides a way to measure the time spent in the code between two points.

This command runs the CPU benchmark tests that collect these statistics:

- FireWall Lock Statistics
- Outbound Packets Statistics
- Inbound Packets Statistics.

**Note** - This command writes the output of these tests to the `dmesg`.

#### Important:

- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.

### Syntax

```
fw [-d] ctl bench
    -h
    lock
        [{ioctl | packet} [<Limit>]]
        [stop]
    packet [{<Limit> | stop}]
```

### Parameters

| Parameter | Description                                                                                                                                                                                                                                                                                                                                |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d        | Runs the command in debug mode.<br>Use only if you troubleshoot the command itself.<br> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session. |
| -h        | Shows the built-in help.                                                                                                                                                                                                                                                                                                                   |

| Parameter                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## fw ctl block

### Description

Blocks all connections to, from, and through the Security Gateway.

 **Important** - The "fw ctl block on" command immediately blocks all connections without a prompt and regardless the currently installed policy. To unblock the connections, you must either reboot the Security Gateway, or connect to the Security Gateway over a serial console (or Lights Out Management Card) and run the "fw ctl block off" command.

 **Important:**

- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.

### Syntax

```
fw [-d] ctl block  
    off  
    on
```

### Parameters

| Parameter | Description                                                                                                                                                                                                                                                                                                                                            |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d        | <p>Runs the command in debug mode.<br/>Use only if you troubleshoot the command itself.</p> <p> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p> |
| off       | Removes the block of all connections.                                                                                                                                                                                                                                                                                                                  |
| on        | Blocks all connections.                                                                                                                                                                                                                                                                                                                                |

## fw ctl chain

### Description

Shows the list of Firewall Chain Modules.

This list shows various inspection Chain Modules, through which the traffic passes on this Security Gateway.

The available Chain Modules depend on the configuration and enabled Software Blades.

#### Important:

- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.

### Syntax

```
fw [-d] ctl chain
```

### Parameters

| Parameter | Description                                                                                                                                                                                                                                                                                                                                               |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d        | <p>Runs the command in debug mode.</p> <p>Use only if you troubleshoot the command itself.</p> <p> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p> |

## Example

```

## fw ctl conn

### Description

Shows the list of Firewall Connection Modules.

This list shows various inspection Connection Modules, through which the traffic passes on this Security Gateway.

The available Connection Modules depend on the configuration and enabled Software Blades.

#### Important:

- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.

### Syntax

```
fw [-d] ctl conn
```

### Parameters

| Parameter | Description                                                                                                                                                                                                                                                                                                                                               |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d        | <p>Runs the command in debug mode.</p> <p>Use only if you troubleshoot the command itself.</p> <p> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p> |

## Example

```
[Expert@MyGW:0]# fw ctl conn
Registered connections modules:

## fw ctl conntab

### Description

Shows formatted list of current connections from the **Connections** kernel table (ID 8158).

Use this command if you want to see the simplified information about the current connections.

### ★ Best Practices:

- Use the "fw ctl conntab" command to see the simplified information about the current connections.
- Use the "fw tab -t connections -f" command (["fw tab" on page 1264](#)) to see the detailed (and more technical) information about the current connections.

### i Important:

- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- On Scalable Platforms, you must connect to the applicable Security Group.

### Syntax

**i Important** - You can specify many parameters at the same time.

```
fw ctl conntab {-h | -help}

fw [-d] ctl conntab [-x [-y]]
    -sip=<Source IP Address in Decimal Format>
    -sport=<Port Number in Decimal Format>
    -dip=<Destination IP Address>
    -dport=<Port Number in Decimal Format>
    -proto=<Protocol Number in Decimal Format>
    -service=<Name of Service>
    -rule=<Rule Number in Decimal Format>
    -state=<State>
    -type=<Bitmask for 'R_CTYPE'>
    -flags=<Bitmask for 'R_CFLAGS'>
```

### Parameters

| Parameter | Description               |
|-----------|---------------------------|
| -h        | Shows the built-in usage. |
| -help     |                           |

| Parameter                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d                                              | <p>Runs the command in debug mode.</p> <p>Use only if you troubleshoot the command itself.</p> <p> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p>                                                                         |
| -x [-y]                                         | <p>Deletes entries that match the specified filters.</p> <p>Without this parameter "-x", the command only shows entries that match the specified filters.</p> <p>The parameter "-y" specifies not to show a prompt before Security Gateway executes this command.</p>                                                                                                                                                           |
| -sip=<Source IP Address in Decimal Format>      | <p>Filters the output by the specified Source IP address.</p> <p> <b>Note</b> - The value can be a range of IP addresses: &lt;IP_address_1&gt;-&lt;IP_address_2&gt;</p> <p>Examples:</p> <ul style="list-style-type: none"> <li>-sip=192.168.3.57</li> <li>-sip=192.168.3.55-192.168.3.66</li> </ul>                                           |
| -sport=<Port Number in Decimal Format>          | <p>Filters the output by the specified Source Port number. See <a href="#">IANA Service Name and Port Number Registry</a>.</p> <p> <b>Note</b> - The value can be a range of port numbers: &lt;port_1&gt;-&lt;port_2&gt;</p> <p>Examples:</p> <ul style="list-style-type: none"> <li>■ -sport=35598</li> <li>■ -sport=33000-33320</li> </ul> |
| -dip=<Destination IP Address in Decimal Format> | <p>Filters the output by the specified Destination IP address.</p> <p> <b>Note</b> - The value can be a range of IP addresses: &lt;IP_address_1&gt;-&lt;IP_address_2&gt;</p> <p>Examples:</p> <ul style="list-style-type: none"> <li>■ -dip=192.168.3.57</li> <li>■ -dip=192.168.3.55-192.168.3.66</li> </ul>                                |
| -dport=<Port Number in Decimal Format>          | <p>Filters the output by the specified Destination Port number. See <a href="#">IANA Service Name and Port Number Registry</a>.</p> <p> <b>Note</b> - The value can be a range of port numbers: &lt;port_1&gt;-&lt;port_2&gt;</p> <p>Examples:</p> <ul style="list-style-type: none"> <li>■ -dport=80</li> <li>■ -dport=80-88</li> </ul>     |

| Parameter                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Examples

### Example 1 - Default output

```
[Expert@MyGW:0]# fw ctl conntab
<(inbound, src=[192.168.204.1,54201], dest=[192.168.204.40,22], TCP); 3593/3600, rule=2, tcp state=TCP_ESTABLISHED, service=ssh(481),
Ifncin=1, Ifncout=1, conn modules: Authentication, FG-1>
<(outbound, src=[192.168.204.40,59249], dest=[192.168.204.1,53], UDP); 20/40, rule=0, service=domain-udp(335), Ifnsout=1, conn
modules: Authentication, FG-1>
<(outbound, src=[192.168.204.40,37892], dest=[192.168.204.1,53], UDP); 20/40, rule=0, service=domain-udp(335), Ifnsin=1, Ifnsout=1,
conn modules: Authentication, FG-1>
[Expert@MyGW:0]#
```

## Example 2 - Filter by a destination port

```
[Expert@MyGW:0]# fw ctl conntab -dport=22
<(inbound, src=[192.168.204.1,54201], dest=[192.168.204.40,22], TCP); 3594/3600, rule=2, tcp state=TCP_ESTABLISHED, service=ssh(481),
Ifncin=1, Ifncout=1, conn modules: Authentication, FG-1>
[Expert@MyGW:0]#
```

## Example 3 - Filter by a destination port

```
[Expert@MyGW:0]# fw ctl conntab -dport=53
<(outbound, src=[192.168.204.40,33585], dest=[192.168.204.1,53], UDP); 39/40, rule=0, service=domain-udp(335), Ifnsout=1, conn
modules: Authentication, FG-1>
<(outbound, src=[192.168.204.40,56661], dest=[192.168.204.1,53], UDP); 39/40, rule=0, service=domain-udp(335), Ifnsin=1, Ifnsout=1,
conn modules: Authentication, FG-1>
[Expert@MyGW:0]#
```

## Example 4 - Filter by a source port

```
[Expert@MyGW:0]# fw ctl conntab -sport=54201
<(inbound, src=[192.168.204.1,54201], dest=[192.168.204.40,22], TCP); 3600/3600, rule=2, tcp state=TCP_ESTABLISHED, service=ssh(481),
Ifncin=1, Ifncout=1, conn modules: Authentication, FG-1>
[Expert@MyGW:0]#
```

## Example 5 - Filter by a protocol

```
[Expert@MyGW:0]# fw ctl conntab -proto=UDP
<(outbound, src=[192.168.204.40,44966], dest=[192.168.204.1,53], UDP); 37/40, rule=0, service=domain-udp(335), Ifnsin=1, Ifnsout=1,
conn modules: Authentication, FG-1>
[Expert@MyGW:0]#
```

```
[Expert@MyGW:0]# fw ctl conntab -proto=11
<(outbound, src=[192.168.204.40,44966], dest=[192.168.204.1,53], UDP); 37/40, rule=0, service=domain-udp(335), Ifnsin=1, Ifnsout=1,
conn modules: Authentication, FG-1>
[Expert@MyGW:0]#
```

## Example 6 - Filter by a protocol

```
[Expert@MyGW:0]# fw ctl conntab -proto=TCP
<(inbound, src=[192.168.204.1,54201], dest=[192.168.204.40,22], TCP); 3596/3600, rule=2, tcp state=TCP_ESTABLISHED, service=ssh(481),
Ifncin=1, Ifncout=1, conn modules: Authentication, FG-1>
[Expert@MyGW:0]#
```

```
[Expert@MyGW:0]# fw ctl conntab -proto=6
<(inbound, src=[192.168.204.1,54201], dest=[192.168.204.40,22], TCP); 3596/3600, rule=2, tcp state=TCP_ESTABLISHED, service=ssh(481),
Ifncin=1, Ifncout=1, conn modules: Authentication, FG-1>
[Expert@MyGW:0]#
```

## Example 7 - Filter by a service

```
[Expert@MyGW:0]# fw ctl conntab -service=domain-udp
<(outbound, src=[192.168.204.40,44966], dest=[192.168.204.1,53], UDP); 35/40, rule=0, service=domain-udp(335), Ifnsin=1, Ifnsout=1,
conn modules: Authentication, FG-1>
[Expert@MyGW:0]#
```

## Example 8 - Filter by a rule number

```
[Expert@MyGW:0]# fw ctl conntab -rule=2
<(inbound, src=[192.168.204.1,54201], dest=[192.168.204.40,22], TCP); 3597/3600, rule=2, tcp state=TCP_ESTABLISHED, service=ssh(481),
Ifncin=1, Ifncout=1, conn modules: Authentication, FG-1>
[Expert@MyGW:0]#
```

## Example 9 - Filter by a destination IP address, destination port, protocol, and service

```
[Expert@MyGW:0]# fw ctl conntab -dip=192.168.204.40 -dport=22 -proto=TCP -service=ssh
<(inbound, src=[192.168.204.1,54201], dest=[192.168.204.40,22], TCP); 3599/3600, rule=2, tcp state=TCP_ESTABLISHED, service=ssh(481),
Ifncin=1, Ifncout=1, conn modules: Authentication, FG-1>
[Expert@MyGW:0]#
```

**Example 10 - Formatted detailed output from the Connections table (for comparison)**

```
[Expert@MyGW:0]# fw tab -t connections -f

Formatting table's data - this might take a while...

```

## fw ctl cpasstat

### Description

Generates statistics report about Check Point Active Streaming (CPAS).

#### Important:

- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- On Scalable Platforms, you must connect to the applicable Security Group.

### Syntax

```
fw [-d] ctl cpasstat [-r]
```

### Parameters

| Parameter | Description                                                                                                                                                                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d        | <p>Runs the command in debug mode.<br/>Use only if you troubleshoot the command itself.</p> <p>★ <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p> |
| -r        | Resets the counters.                                                                                                                                                                                                                                                 |

## 'fw ctl debug' and 'fw ctl kdebug'

### Description

These commands generate kernel debug messages from Check Point Firewall kernel to a debug buffer.

For more information, see the [R82.10 Security Gateway Guide](#) - Chapter *Kernel Debug on Security Gateway*.

## fw ctl dlpkstat

### Description

Generates statistics report about Data Loss Prevention, inspected HTTP requests, and Identity Awareness Captive Portal.

This report contains these statistics:

| Category                                    | Information                                             |
|---------------------------------------------|---------------------------------------------------------|
| DLP Kernel Statistics Information           | Emails and HTTP requests                                |
| User Mode Responses Statistics              | Emails and HTTP requests                                |
| Identity Awareness - Captive Portal         | HTTP requests redirected to the Captive Portal          |
| Identity Awareness - Fetch Users Statistics | Synchronous and asynchronous Identity Awareness queries |

**Best Practice** - This report is very useful when you:

- Debug problems with HTTP protocol that occur under traffic stress.
- Examine the traffic shape (for example, to know how many HTTP "POST" and HTTP "GET" requests pass through the Security Gateway).

**Important:**

- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- On Scalable Platforms, you must connect to the applicable Security Group.

### Syntax

```
fw [-d] ctl dlpkstat [-r]
```

## Parameters

| Parameter | Description                                                                                                                                                                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d        | <p>Runs the command in debug mode.<br/>Use only if you troubleshoot the command itself.</p> <p>★ <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p> |
| -r        | Resets the counters.                                                                                                                                                                                                                                                 |

## fw ctl get

### Description

Shows the current value of the specified kernel parameter.

#### Important:

- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.
- In a VSX Gateway, the configured values of kernel parameters apply to all existing Virtual Systems and Virtual Routers.

#### Notes:

- Kernel parameters let you change the advanced behavior of your Security Gateway.
- There are two types of kernel parameters - *integer* and *string*.
- Security Gateway gets the names and the default values of the kernel parameters from these kernel module files:
  - \$FWDIR/boot/modules/fw\_kern\_64.o
  - \$FWDIR/boot/modules/fw\_kern\_64\_v6.o
  - \$FWDIR/boot/modules/fw\_kern\_64\_3\_10\_64.o
  - \$FWDIR/boot/modules/fw\_kern\_64\_3\_10\_64\_v6.o
  - \$PPKDIR/boot/modules/sim\_kern\_64.o
  - \$PPKDIR/boot/modules/sim\_kern\_64\_v6.o
  - \$PPKDIR/boot/modules/sim\_kern\_64\_3\_10\_64.o
  - \$PPKDIR/boot/modules/sim\_kern\_64\_3\_10\_64\_v6.o
- Refer to the related command ["fw ctl set" on page 1145](#).
- Refer to the related article [sk33156: Creating a file with all the kernel parameters and their values](#).
- See the [R82.10 Security Gateway Guide](#) > Chapter "Working with Kernel Parameters".

### Syntax

```
fw [-d] ctl get
    int <Name of Integer Kernel Parameter> [-a]
    str <Name of String Kernel Parameter> [-a]
```

## Parameters

| Parameter                                       | Description                                                                                                                                                                                                                                                                                                                              |
|-------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d                                              | Runs the command in debug mode.<br>Use only if you troubleshoot the command itself.<br> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session. |
| <i>&lt;Name of Integer Kernel Parameter&gt;</i> | Specifies the name of the integer kernel parameter.                                                                                                                                                                                                                                                                                      |
| <i>&lt;Name of String Kernel Parameter&gt;</i>  | Specifies the name of the string kernel parameter.                                                                                                                                                                                                                                                                                       |
| -a                                              | Specifies to search for this kernel parameter in this order: <ol style="list-style-type: none"> <li>1. In \$FWDIR/boot/modules/fw_*.o</li> <li>2. In \$PPKDIR/boot/modules/sim_*.o</li> </ol>                                                                                                                                            |

### Example for an integer kernel parameter

```
[Expert@MyGW:0]# fw ctl get int fw_kdprintf_limit -a
FW:
fw_kdprintf_limit = 100
PPAK 0: fw_kdprintf_limit = 10
[Expert@MyGW:0]#
```

### Example for a string kernel parameter

```
[Expert@MyGW:0]# fw ctl get str fileapp_default_encoding_charset -a
FW:
fileapp_default_encoding_charset = 'UTF-8'
PPAK 0: Get failed.
[Expert@MyGW:0]#
```

## fw ctl iflist

### Description

Shows the list with this information:

- The name of interfaces, to which the Check Point Firewall kernel attached.
- The internal numbers of the interfaces in the Check Point Firewall kernel.

#### Notes:

- This list shows all detected interfaces, even if there are no IP addresses assigned on them.
- You use this list when you analyze a kernel debug, which shows only the internal numbers of the interfaces (for example, `ifn=2`).
- Related "[cpstat](#) on page 1033" commands:
  - `cpstat -f ifconfig os`
  - `cpstat -f interfaces fw`

#### Important:

- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- On Scalable Platforms, you must connect to the applicable Security Group.

### Syntax

```
fw [-d] ctl iflist
```

### Parameters

| Parameter | Description                                                                                                                                                                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d        | <p>Runs the command in debug mode.<br/>Use only if you troubleshoot the command itself.</p> <p>★ <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p> |

## Example

```
[Expert@MyGW:0]# fw ctl iflist
fw ctl iflist
1 : eth0
2 : eth1
3 : eth2
4 : eth3
5 : eth4
6 : eth5
7 : eth6
8 : eth7
[Expert@MyGW:0]#
```

## fw ctl install

### Description

Tells the operating system to start passing packets to Firewall.

This command runs automatically when the Security Gateway or an administrator runs the ["cpstart" on page 1032](#) command.

 **Warning** - If you run the ["fw ctl uninstall" on page 1151](#) command and then the "fw ctl install" command, it does **not** restore the Security Policy. You must run one of these commands: ["fw fetch" on page 1154](#), or ["cpstart" on page 1032](#).

 **Important:**

- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.

### Syntax

```
fw [-d] ctl install
```

### Parameters

| Parameter | Description                                                                                                                                                                                                                                                                                                                                            |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d        | <p>Runs the command in debug mode.<br/>Use only if you troubleshoot the command itself.</p> <p> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p> |

## fw ctl leak

### Description

Generates leak detection report. This report is for Check Point use only.

#### Important:

- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.
- This command saves the report into the active `/var/log/messages` file and the `dmesg` buffer.

### Syntax

```
fw [-d] ctl leak
    {-h | -help}
    [{-a | -A}] [-t <Internal Object Type>] [-o <Internal Object
ID>]
    [-d] [-l] [-p]
    [-s]
```

### Parameters

| Parameter                          | Description                                                                                                                                                                                                                                                                                                                                |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>fw -d ctl leak</code><br>... | Runs the command in debug mode.<br>Use only if you troubleshoot the command itself.<br> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session. |
| <code>{-h   -help}</code>          | Shows the built-in help.                                                                                                                                                                                                                                                                                                                   |
| <code>-a</code>                    | Specifies to perform leak detection for potential leaks.<br>This parameter is mutually exclusive with the parameter " <code>-A</code> ".                                                                                                                                                                                                   |
| <code>-A</code>                    | Specifies to perform leak detection for all leaks.<br>This parameter is mutually exclusive with the parameter " <code>-a</code> ".                                                                                                                                                                                                         |
| <code>-d</code>                    | Dumps object data.<br>This parameter is mutually exclusive with the parameter " <code>-s</code> ".                                                                                                                                                                                                                                         |

| Parameter                 | Description                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -l                        | Prints the action log.<br>This parameter is mutually exclusive with the parameter "-s".                                                                                                                                                                                                                                                                                     |
| -o <Internal Object ID>   | Specifies to perform leak detection for the specified internal object ID.                                                                                                                                                                                                                                                                                                   |
| -p                        | Purges the internal objects from the lists.<br>This parameter is mutually exclusive with the parameter "-s".                                                                                                                                                                                                                                                                |
| -s                        | Shows summary only.<br>This parameter is mutually exclusive with the parameters "-d", "-l", and "-p".                                                                                                                                                                                                                                                                       |
| -t <Internal Object Type> | Specifies the internal object types, for which to perform leak detection.<br>Available internal object types are: <ul style="list-style-type: none"> <li>■ chain</li> <li>■ connh</li> <li>■ cookie</li> <li>■ kbuf</li> <li>■ num</li> </ul> If you do not specify the internal object type explicitly, the command performs leak detection for all internal object types. |

## Procedure

| Step | Instructions                                                                                                                                   |
|------|------------------------------------------------------------------------------------------------------------------------------------------------|
| 1    | Connect to the command line on the Security Gateway.                                                                                           |
| 2    | Log in to the Expert mode.                                                                                                                     |
| 3    | Back up the current <code>/var/log/messages</code> file: <pre>[Expert@GW_HostName:0]# cp -v /var/log/messages{, _BKP}</pre>                    |
| 4    | Delete the information from the current <code>/var/log/messages</code> file: <pre>[Expert@GW_HostName:0]# echo '' &gt; /var/log/messages</pre> |

| Step | Instructions                                                                                                                                                 |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5    | Delete the information from the current <i>dmesg</i> buffer: <pre>[Expert@GW_HostName:0]# dmesg -c</pre>                                                     |
| 6    | Generate the leak detection report (see the <b>Syntax</b> section above): <pre>[Expert@GW_HostName:0]# fw [-d] ctl leak &lt;options&gt;</pre>                |
| 7    | Make sure the command generated the leak detection report: <pre>[Expert@GW_HostName:0]# dmesg</pre> <pre>[Expert@GW_HostName:0]# cat /var/log/messages</pre> |
| 8    | Collect the leak detection report: <pre>[Expert@GW_HostName:0]# cp -v /var/log/messages{,_LEAK_DETECTION}</pre>                                              |
| 9    | Analyze the leak detection report: <pre>/var/log/messages_LEAK_DETECTION</pre>                                                                               |

## Example

```
[Expert@MyGW:0]# cp -v /var/log/messages{, _BKP}
`/var/log/messages' -> `/var/log/messages_BKP'
[Expert@MyGW:0]#
[Expert@MyGW:0]# echo '' > /var/log/messages
[Expert@MyGW:0]#
[Expert@MyGW:0]# dmesg -c
[Expert@MyGW:0]#
[Expert@MyGW:0]# fw ctl leak -s
[Expert@MyGW:0]#
[Expert@MyGW:0]# dmesg

[Expert@MyGW:0]# cp -v /var/log/messages{, _LEAK_DETECTION}
`/var/log/messages' -> `/var/log/messages_LEAK_DETECTION'
[Expert@MyGW:0]#
```

## fw ctl pstat

### Description

Shows Security Gateway various internal statistics:

- System Capacity Summary
- Hash kernel memory (hmem) statistics
- System kernel memory (smem) statistics
- Kernel memory (kmem) statistics
- Cookies
- Connections
- Fragments
- NAT
- Handles

#### Important:

- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- On Scalable Platforms, you must connect to the applicable Security Group.

### Syntax

 **Important** - You can specify many parameters at the same time.

```
fw [-d] ctl pstat [-c] [-h] [-k] [-l] [-m] [-o] [-s] [-v {4 | 6}]
```

### Parameters

| Parameter | Description                                                                                                                                                                                                                                                                                                                                            |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d        | <p>Runs the command in debug mode.<br/>Use only if you troubleshoot the command itself.</p> <p> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p> |

| Parameter    | Description                                                                                                                                                                                                                                                                                   |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -c           | Shows detailed CoreXL Dispatcher statistics: <ul style="list-style-type: none"> <li>▪ <code>fwmultik_global_stats</code> splits for each CoreXL Firewall instance.</li> <li>▪ <code>fwmultik_gconn_stats</code> for each CPU.</li> <li>▪ <code>fwmultik_stats</code> for each CPU.</li> </ul> |
| -h           | Shows additional Hash kernel memory (hmem) statistics.                                                                                                                                                                                                                                        |
| -k           | Shows additional Kernel memory (kmem) statistics.                                                                                                                                                                                                                                             |
| -l           | Shows Handles statistics.                                                                                                                                                                                                                                                                     |
| -m           | Shows general CoreXL Dispatcher statistics.                                                                                                                                                                                                                                                   |
| -o           | Shows additional Cookies statistics.                                                                                                                                                                                                                                                          |
| -s           | Shows additional System kernel memory (smem) statistics.                                                                                                                                                                                                                                      |
| -v 4<br>-v 6 | Shows statistics for IPv4 (-v 4) traffic only, or for IPv6 (-v 6) traffic only. Default is to show statistics for both IPv4 and IPv6 traffic.                                                                                                                                                 |

## Examples

### Example 1 - fw ctl pstat

```
[Expert@MyGW:0]# fw ctl pstat

System Capacity Summary:
  Memory used: 3% (265 MB out of 7117 MB) - below watermark
  Concurrent Connections: Not Available
  Aggressive Aging is enabled, not active

Hash kernel memory (hmem) statistics:
  Total memory allocated: 742391808 bytes in 181248 (4096 bytes) blocks using 1 pool
  Total memory bytes used:          0 unused: 742391808 (100.00%) peak: 68247020
  Total memory blocks used:          0 unused: 181248 (100%) peak: 17227
  Allocations: 2193027 alloc, 0 failed alloc, 2154121 free

System kernel memory (smem) statistics:
  Total memory bytes used: 913975068 peak: 1165010872
  Total memory bytes wasted: 7883999
  Blocking memory bytes used: 4896272 peak: 6916084
  Non-Blocking memory bytes used: 909078796 peak: 1158094788
  Allocations: 13217 alloc, 0 failed alloc, 10027 free, 0 failed free
  vmalloc bytes used: 908585924 expensive: no

Kernel memory (kmem) statistics:
  Total memory bytes used: 185761552 peak: 486615148
  Allocations: 2204456 alloc, 0 failed alloc
  2162587 free, 0 failed free
  External Allocations: 0 for packets, 7303643 for SXL

Cookies:
  91808 total, 0 alloc, 0 free,
  2 dup, 91808 get, 0 put,
  182258 len, 909 cached len, 0 chain alloc,
  0 chain free

Connections:
  0 total, 0 TCP, 0 UDP, 0 ICMP,
  0 other, 0 anticipated, 0 recovered, -3 concurrent,
  0 peak concurrent

Fragments:
  0 fragments, 0 packets, 0 expired, 0 short,
  0 large, 0 duplicates, 0 failures

NAT:
  0/0 forw, 0/0 bckw, 0 tcpudp,
  0 icmp, 0-0 alloc

Sync: Run "cphaprob syncstat" for cluster sync statistics.

[Expert@MyGW:0]#
```

## fw ctl set

### Description

Configures the specified value for the specified kernel parameter.

#### Important:

- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.
- In a VSX Gateway, the configured values of kernel parameters apply to all existing Virtual Systems and Virtual Routers.
- The configuration made with this command **without** the "-f" flag does **not** survive reboot.  
To make this configuration permanent, you must edit one of the applicable configuration files:
  - \$FWDIR/boot/modules/fw\_kern.conf
  - \$PPKDIR/conf/simkern.conf
- See the [R82.10 Security Gateway Guide](#) > Chapter "Working with Kernel Parameters".

#### Notes:

- Kernel parameters control the advanced behavior of your Security Gateway.
- There are two types of kernel parameters - *integer* and *string*.
- Security Gateway gets the names and the default values of the kernel parameters from these kernel module files:
  - \$FWDIR/boot/modules/fw\_kern\_64\_3\_10\_64.o
  - \$FWDIR/boot/modules/fw\_kern\_64\_3\_10\_64\_v6.o
  - \$FWDIR/boot/modules/fw\_kern\_64\_3\_10\_64\_sp.o
  - \$FWDIR/boot/modules/fw\_kern\_64\_3\_10\_64\_sp\_v6.o
  - \$PPKDIR/boot/modules/adp\_kern\_64\_3\_10\_64.o
  - \$PPKDIR/boot/modules/sim\_kern\_64\_3\_10\_64.o
  - \$PPKDIR/boot/modules/sim\_kern\_64\_3\_10\_64\_v6.o
- Refer to the related command ["fw ctl get" on page 1133](#).
- Refer to the related article [sk33156: Creating a file with all the kernel parameters and their values](#).
- See the [R82.10 Security Gateway Guide](#) > Chapter "Working with Kernel Parameters".

## Syntax on a Security Gateway / Cluster Member in Gaia Clish or the Expert mode

```
fw [-d] ctl set [-f] int <Name of Integer Kernel Parameter>
<Integer Value>
```

```
fw [-d] ctl set [-f] str <Name of String Kernel Parameter>
'<String Value>'
```

## Syntax on a Scalable Platform Security Group in the Expert mode

On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

- To make the change only in the current session (does not survive reboot):

```
g_fw [-d] ctl set int <Name of Integer Kernel Parameter>
<Integer Value>
```

```
g_fw [-d] ctl set str <Name of String Kernel Parameter>
'<String Value>'
```

- To make the change that survives reboot:

```
g_update_conf_file <Path to File> <Name of Integer Kernel
Parameter>=<Integer Value>
```

```
g_update_conf_file <Path to File> <Name of String Kernel
Parameter>='<String Value>'
```

## Parameters

| Parameter                          | Description                                                                                                                                                                                                                                                                                  |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d                                 | <p>Runs the command in debug mode.</p> <p>Use only if you troubleshoot the command itself.</p> <p>★ <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p>                      |
| -f                                 | <p>Automatically makes the required changes in the corresponding configuration file to survive reboot:</p> <ul style="list-style-type: none"> <li>▪ \$FWDIR/boot/modules/fwkern.conf</li> <li>▪ \$PPKDIR/conf/simkern.conf</li> </ul> <p>This flag does not apply to Scalable Platforms.</p> |
| <Name of Integer Kernel Parameter> | Specifies the name of the integer kernel parameter.                                                                                                                                                                                                                                          |
| <Integer Value>                    | Specifies the integer value for the integer kernel parameter.                                                                                                                                                                                                                                |
| <Name of String Kernel Parameter>  | Specifies the name of the string kernel parameter.                                                                                                                                                                                                                                           |
| '<String Value>'                   | Specifies the string value for the string kernel parameter.                                                                                                                                                                                                                                  |
| <Path to File>                     | <p>Specifies the path to the configuration file on Scalable Platforms:</p> <ul style="list-style-type: none"> <li>▪ \$FWDIR/boot/modules/fwkern.conf</li> <li>▪ \$PPKDIR/conf/simkern.conf</li> </ul>                                                                                        |

### Example for an integer kernel parameter (does not survive reboot)

```
[Expert@MyGW:0]# fw ctl get int fw_kdprintf_limit
fw_kdprintf_limit = 100
[Expert@MyGW:0]#
[Expert@MyGW:0]# fw ctl set int fw_kdprintf_limit 50
[Expert@MyGW:0]#
[Expert@MyGW:0]# fw ctl get int fw_kdprintf_limit
fw_kdprintf_limit = 50
[Expert@MyGW:0]#
```

## Example for an integer kernel parameter (survives reboot)

```
[Expert@MyGW:0]# fw ctl get int fw_kdprintf_limit
fw_kdprintf_limit = 100
[Expert@MyGW:0]#
[Expert@MyGW:0]# fw ctl set -f int fw_kdprintf_limit 50
"fwkern.conf" was updated successfully
[Expert@MyGW:0]#
[Expert@MyGW:0]# fw ctl get int fw_kdprintf_limit
fw_kdprintf_limit = 50
[Expert@MyGW:0]#
```

## Example for a string kernel parameter

```
[Expert@MyGW:0]# fw ctl set str icap_unwrap_append_header_str '__print__'
[Expert@MyGW:0]#
[Expert@MyGW:0]# fw ctl get str icap_unwrap_append_header_str
icap_unwrap_append_header_str = '__print__'
[Expert@MyGW:0]#
[Expert@MyGW:0]# fw ctl set str icap_unwrap_append_header_str ''
[Expert@MyGW:0]#
[Expert@MyGW:0]# fw ctl get str icap_unwrap_append_header_str
icap_unwrap_append_header_str = ''
[Expert@MyGW:0]#
```

## fw ctl tcpstrstat

### Description

Generates statistics report about TCP Streaming.

#### Important:

- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- On Scalable Platforms, you must connect to the applicable Security Group.

### Syntax

```
fw [-d] ctl tcpstrstat  
    [-p]  
    [-r]
```

### Parameters

| Parameter | Description                                                                                                                                                                                                                                                                                                                                |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d        | Runs the command in debug mode.<br>Use only if you troubleshoot the command itself.<br> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session. |
| -p        | Shows verbose statistics.                                                                                                                                                                                                                                                                                                                  |
| -r        | Resets the counters.                                                                                                                                                                                                                                                                                                                       |

## Example 1 - Default output

```
[Expert@MyGW:0]# fw ctl tcpstrstat

[Expert@MyGW:0]#
```

## fw ctl uninstall

### Description

1. Tells the operating system to stop passing packets to Firewall.
2. Unloads the current Security Policy.
3. Unloads the current Firewall Chain Modules (see ["fw ctl chain" on page 1113](#)).
4. Unloads the current Firewall Connection Modules except for RTM (see ["fw ctl conn" on page 1115](#)).

### Warnings:

1. If you run the "fw ctl uninstall" command, the networks behind the Security Gateway become unprotected.
2. If you run the "fw ctl uninstall" command and then the ["fw ctl install" on page 1137](#) command, it does not restore the Security Policy.  
You must run one of these commands: ["fw fetch" on page 1154](#), or ["cpstart" on page 1032](#).

### Important:

- You can run this command in the Expert mode or in Gaia Clish.
- On Scalable Platforms, use the command "asg policy unload".  
See the [R82.10 Scalable Platforms Administration Guide](#).

### Syntax

```
fw [-d] ctl uninstall
```

### Parameters

| Parameter | Description                                                                                                                                                                                                                                                                                                                                            |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d        | <p>Runs the command in debug mode.<br/>Use only if you troubleshoot the command itself.</p> <p> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p> |

# fw defaultgen

## Description

Manually generates the Default Filter policy files.

Refer to these related commands:

- ["comp\\_init\\_policy" on page 964](#)
- ["control\\_bootsec" on page 979](#)
- ["fwboot default" on page 1313](#)
- ["fwboot bootconf" on page 1300](#)

## Important:

- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.

## Syntax

```
fw [-d] defaultgen
```

## Parameters

| Parameter  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d         | <p>Runs the command in debug mode.<br/>Use only if you troubleshoot the command itself.</p> <p> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p>                                                                                                                                                                     |
| defaultgen | <p>Generates the Default Filter policy files:</p> <ul style="list-style-type: none"> <li>▪ For IPv4 traffic: <div style="border: 1px solid #ccc; padding: 2px; margin: 5px 0;">\$FWDIR/state/default.bin</div> </li> <li>▪ For IPv6 traffic: <div style="border: 1px solid #ccc; padding: 2px; margin: 5px 0;">\$FWDIR/state/default.bin6</div> </li> </ul> <p>If the Default Filter policy file already exists, the command creates a backup copy (\$FWDIR/state/default.bin.bak and \$FWDIR/state/default.bin6.bak).</p> |

## Example

```
[Expert@MyGW:0]# fw defaultgen
Generating default filter
defaultfilter:
Compiled OK.
defaultfilter:
Compiled OK.
  Backing up default.bin as default.bin.bak
  hostaddr(MyGW) failed
  Backing up default.bin6 as default.bin6.bak
[Expert@MyGW:0]#
```

# fw fetch

## Description

Fetches the Security Policy from the specified host and installs it to the kernel.

### Important:

- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- On Scalable Platforms, you must connect to the applicable Security Group.

## Syntax

- To fetch the policy from the Management Server:

```
fw [-d] fetch -f [-i] [-n] [-r]
```

- To fetch the policy from a peer Cluster Member, and, if it fails, then from the Management Server:

```
fw [-d] fetch -f -c [-i] [-n] [-r]
```

- To fetch the policy from the specified Check Point server(s):

```
fw [-d] fetch [-i] [-n] [-r] <Master 1> [<Master 2> ...]
```

- To fetch the policy stored locally on the Security Gateway in the default directory \$FWDIR/state/:

```
fw [-d] fetch local [-nu]
```

```
fw [-d] fetch localhost [-nu]
```

- To fetch the policy stored locally on the Security Gateway in the specified directory:

```
fw [-d] fetchlocal -d <Full Path to Directory>
```

## Parameters

| Parameter                   | Description                                                                                                                                                                                                                                                                                               |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>fw -d fetch...</code> | <p>Runs the command in debug mode.<br/>Use only if you troubleshoot the command itself.</p> <p>★ <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p>                                      |
| <code>-a</code>             | Installs policy on non-SMO Security Group Members.                                                                                                                                                                                                                                                        |
| <code>-c</code>             | <p>Specifies that you fetch the policy from a peer Cluster Member.</p> <p>ℹ <b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ Must also use the "-f" parameter.</li> <li>▪ Works only in cluster.</li> </ul>                                                                                     |
| <code>-f</code>             | Specifies that you fetch the policy from a Management Server listed in the <code>\$FWDIR/conf/masters</code> file.                                                                                                                                                                                        |
| <code>-i</code>             | On a Security Gateway with dynamically assigned IP address (DAIP), specifies to ignore the SIC name and object name.                                                                                                                                                                                      |
| <code>-n</code>             | Specifies not to load the fetched policy, if it is the same as the policy already located on the Security Gateway.                                                                                                                                                                                        |
| <code>-nu</code>            | Specifies not to update the currently installed policy.                                                                                                                                                                                                                                                   |
| <code>-r</code>             | <p>On a Cluster Member, specifies to ignore this option in SmartConsole <b>Install Policy</b> window:<br/><b>For gateway clusters, if installation on a cluster member fails, do not install on that cluster</b></p> <p>★ <b>Best Practice</b> - Use this parameter if a peer Cluster Member is Down.</p> |
| <code>-s</code>             | Installs policy on a Scalable Platform Security Group.                                                                                                                                                                                                                                                    |

| Parameter                                                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

# fw fetchlogs

## Description

Fetches the specified Security log files (\$FWDIR/log/\*.log\*) or Audit log files (\$FWDIR/log/\*.adtlog\*) from the specified Check Point server.

**Important** - You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).

## Syntax

```
fw [-d] fetchlogs [-f <Name of Log File 1>] [-f <Name of Log File 2>]... [-f <Name of Log File N>] <Target>
```

## Parameters

| Parameter               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d                      | <p>Runs the command in debug mode.</p> <p>Use only if you troubleshoot the command itself.</p> <p>★ <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| -f <Name of Log File N> | <p>Specifies the name of the log file to fetch. Need to specify name only.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>■ If you do not specify the log file name explicitly, the command transfers all Security log files (\$FWDIR/log/*.log*) and all Audit log files (\$FWDIR/log/*.adtlog*).</li> <li>■ The specified log file name can include wildcards * and ? (for example, 2017-0?-*.log).<br/>If you enter a wildcard, you must enclose it in double quotes or single quotes.</li> <li>■ You can specify multiple log files in one command.<br/>You must use the -f parameter for each log file name pattern.</li> <li>■ This command also transfers the applicable log pointer files.</li> </ul> |
| <Target>                | <p>Specifies the remote Check Point server, with which this local Check Point server has established SIC trust.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>■ The local and the remote servers must have established SIC trust.</li> <li>■ The local server can be a Security Management Server, a Log Server, a Cluster Member.</li> <li>■ The remote server can be a Security Gateway, a Cluster Member, a Log Server, or a Security Management Server in High Availability deployment.</li> <li>■ You can specify the remote managed server by its main IP address or Object Name as configured in SmartConsole.</li> </ul>                                                                             |

**Notes:**

- This command moves the specified log files from the `$FWDIR/log/` directory on the specified Check Point server.

Meaning, it deletes the specified log files on the specified Check Point server after it copies them successfully.

- This command moves the specified log files to the `$FWDIR/log/` directory on the local Check Point server, on which you run this command.
- This command cannot fetch the *active* log files `$FWDIR/log/fw.log` or `$FWDIR/log/fw.adtlog`.

To fetch these active log files:

1. Perform the log switch on the applicable Check Point server:

See "[fw logswitch](#)" on page 284.

```
fw logswitch [-audit] [-h <IP Address or Hostname>]
```

2. Fetch the rotated log file from the applicable Check Point server:

```
fw fetchlogs -f <Log File Name> <IP Address or Hostname>
```

- This command renames the log files it fetched from the specified Check Point server.

The new log file name is the concatenation of these:

- The Check Point server's name (as configured in SmartConsole).
- Two underscore (\_\_) characters.
- The original log file name

Example: `MyGW__2019-06-01_000000.log`

## Example - Fetching log files from a Management Server

```
[Expert@HostName:0]# fw lslogs MyGW
Size Log file name
 23KB 2019-05-16_000000.log
   9KB 2019-05-17_000000.log
  11KB 2019-05-18_000000.log
5796KB 2019-06-01_000000.log
4610KB fw.log
[Expert@HostName:0]#

[Expert@HostName:0]# fw fetchlogs -f 2019-06-01_000000 MyGW
File fetching in process. It may take some time...
File MyGW__2019-06-01_000000.log was fetched successfully
[Expert@HostName:0]#

[Expert@HostName:0]# ls $FWDIR/log/MyGW*
/opt/CPsuite-R82.10/fw1/log/MyGW__2019-06-01_000000.log
/opt/CPsuite-R82.10/fw1/log/MyGW__2019-06-01_000000.logaccount_ptr
/opt/CPsuite-R82.10/fw1/log/MyGW__2019-06-01_000000.loginitial_ptr
/opt/CPsuite-R82.10/fw1/log/MyGW__2019-06-01_000000.logptr
[Expert@HostName:0]#

[Expert@HostName:0]# fw lslogs MyGW
Size Log file name
 23KB 2019-05-16_000000.log
   9KB 2019-05-17_000000.log
  11KB 2019-05-18_000000.log
4610KB fw.log
[Expert@HostName:0]#
```

# fw getifs

## Description

Shows the list with this information:

- The name of interfaces, to which the Check Point Firewall kernel attached.
- The IP addresses assigned to the interfaces.

## Notes:

- This list shows only interfaces that have IP addresses assigned on them.
- Related ["cpstat" on page 1033](#) commands:
  - `cpstat -f ifconfig os`
  - `cpstat -f interfaces fw`

## Important:

- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- On Scalable Platforms, you must connect to the applicable Security Group.

## Syntax

```
fw [-d] getifs
```

## Parameters

| Parameter | Description                                                                                                                                                                                                                                                                                                                                            |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d        | <p>Runs the command in debug mode.<br/>Use only if you troubleshoot the command itself.</p> <p> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p> |

## Example

```
[Expert@MyGW:0]# fw getifs
localhost eth0 192.168.30.40 255.255.255.0
localhost eth1 172.30.60.80 255.255.255.0
[Expert@MyGW:0]#
```

# fw hastat

## Description

Shows information about Check Point computers in High Availability configuration and their states.

-  **Note** - This command is outdated. On cluster members, run the Gaia Clish command "show cluster state", or the Expert mode command "cphaprob state".
-  **Note** - This command is outdated. On Management Servers, run the ["cpstat" on page 209](#) command.

## Syntax

```
fw hastat [<Target1>] [<Target2>] ... [<TargetN>]
```

## Parameters

| Parameter                               | Description                                                                                                                                                                                                                                                                                            |
|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <Target1><br><Target2> ...<br><TargetN> | Specifies the Check Point computers to query.<br>If you run this command on the Management Server, you can enter the applicable IP address, or the resolvable HostName of the managed Security Gateway or Cluster Member.<br>If you do not specify the target, the command queries the local computer. |

## Example - Querying the cluster members from the Management Server

```
[Expert@MGMT:0]# fw hastat 192.168.3.52
HOST NUMBER HIGH AVAILABILITY STATE MACHINE STATUS
192.168.3.52 1 active OK
[Expert@MGMT:0]#

[Expert@MGMT:0]# fw hastat 192.168.3.53
HOST NUMBER HIGH AVAILABILITY STATE MACHINE STATUS
192.168.3.53 2 stand-by OK
[Expert@MGMT:0]#

[Expert@MGMT:0]# fw hastat 192.168.3.52 192.168.3.53
HOST NUMBER HIGH AVAILABILITY STATE MACHINE STATUS
192.168.3.52 1 active OK
192.168.3.53 2 stand-by OK
[Expert@MGMT:0]#
```

## Example - Querying the local Cluster Member

```
[Expert@Member1:0]# fw hastat
HOST NUMBER HIGH AVAILABILITY STATE MACHINE STATUS
192.168.3.52 1 active OK
[Expert@Member1:0]#
```

# fw isp\_link

## Description

Controls the state of ISP Links in the ISP Redundancy configuration on Security Gateway.

See the [R82.10 Security Gateway Guide](#).

### Important:

- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- On Scalable Platforms, you must connect to the applicable Security Group.

## Syntax

```
fw [-d] isp_link
    {-h | -help}
    [<Name of Object>] <Name of ISP Link>
    down
    up
```

## Parameters

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d                 | <p>Runs the command in debug mode.</p> <p>Use only if you troubleshoot the command itself.</p> <p>★ <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p>                                                                                           |
| {-h   -help}       | Shows the built-in usage.                                                                                                                                                                                                                                                                                                                                         |
| <Name of Object>   | <p>Only when you run this command on a Management Server:</p> <p>The name of the Security Gateway or Cluster Member object as defined in SmartConsole (from the left navigation panel, click <b>Gateways &amp; Servers</b>).</p>                                                                                                                                  |
| <Name of ISP Link> | <p>The name of the ISP Link as defined in the Security Gateway or Cluster object:</p> <ol style="list-style-type: none"> <li>1. In SmartConsole, from the left navigation panel, click <b>Gateways &amp; Servers</b>.</li> <li>2. Open the Security Gateway or Cluster object.</li> <li>3. From the left tree, click <b>Other &gt; ISP Redundancy</b>.</li> </ol> |
| down               | Changes the state of the specified ISP Link to DOWN.                                                                                                                                                                                                                                                                                                              |
| up                 | Changes the state of the specified ISP Link to UP.                                                                                                                                                                                                                                                                                                                |

# fw kill

## Description

Kills the specified Check Point processes.

### Important:

- Make sure the killed process is restarted, or restart it manually. See [sk97638](#).
- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).

## Syntax

```
fw [-d] kill [-t <Signal Number>] <Name of Process>
```

## Parameters

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d                 | <p>Runs the command in debug mode.</p> <p>Use only if you troubleshoot the command itself.</p> <p> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p>                                                                                      |
| -t <Signal Number> | <p>Specifies which signal to send to the Check Point process.</p> <p>For the list of available signals and their numbers, run the <code>kill -l</code> command.</p> <p>For information about the signals, see the manual pages for the <a href="#">kill</a> and <a href="#">signal</a>.</p> <p>If you do not specify the signal explicitly, the command sends Signal 15 (SIGTERM).</p> <p><b>Note</b> - Processes can ignore some signals.</p> |
| <Name of Process>  | <p>Specifies the name of the Check Point process to kill.</p> <p>To see the names of the processes, run the <code>ps auxwf</code> command.</p>                                                                                                                                                                                                                                                                                                 |

## Example

```
fw kill fwd
```

# fw lichosts

## Description

Shows IP addresses of internal hosts that Security Gateway detected and counted based on the installed license.

### Important:

- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- On Scalable Platforms, you must connect to the applicable Security Group.

## Syntax

```
fw [-d] lichosts [-l] [-x]
```

## Parameters

| Parameter | Description                                                                                                                                                                                                                                                                                                                                |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d        | Runs the command in debug mode.<br>Use only if you troubleshoot the command itself.<br> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session. |
| -l        | Shows the output in the long format.                                                                                                                                                                                                                                                                                                       |
| -x        | Shows the output in the hexadecimal format.                                                                                                                                                                                                                                                                                                |

## Example

```
[Expert@MyGW:0]# fw lichosts
License allows an unlimited number of hosts
[Expert@MyGW:0]
```

## Related SK article

[sk10200 - 'too many internal hosts' error in /var/log/messages on Security Gateway.](#)

# fw log

## Description

Shows the content of Check Point log files - Security (\$FWDIR/log/\*.log) or Audit (\$FWDIR/log/\*.adtlog).

 **Important** - You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).

## Syntax

```
fw log {-h | -help}
```

```
fw [-d] log [-a] [-b "<Start Timestamp>" "<End Timestamp>"] [-c
<Action>] [{-f | -t}] [-g] [-H] [-h <Origin>] [-i] [-k {<Alert
Name> | all}] [-l] [-m {initial | semi | raw}] [-n] [-o] [-p] [-q]
[-S] [-s "<Start Timestamp>"] [-e "<End Timestamp>"] [-u
<Unification Scheme File>] [-w] [-x <Start Entry Number>] [-y <End
Entry Number>] [-z] [-#] [<Log File>]
```

## Parameters

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {-h   -help} | Shows the built-in usage.<br><b>Note</b> - The built-in usage does not show some of the parameters described in this table.                                                                                                                                                                                                                |
| -d           | Runs the command in debug mode.<br>Use only if you troubleshoot the command itself.<br> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session. |
| -a           | Shows only Account log entries.                                                                                                                                                                                                                                                                                                            |

| Parameter                                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| -#                                 | Show confidential logs in clear text.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <Log File>                         | <p>Specifies the log file to read.</p> <p>If you do not specify the log file explicitly, the command opens the <code>\$FWDIR/log/fw.log</code> log file.</p> <p>You can specify a switched log file.</p>                                                                                                                                                                                                                                                                                |

## Date and Time format

| Part of timestamp                                                       | Format                   | Example                   |
|-------------------------------------------------------------------------|--------------------------|---------------------------|
| Date only                                                               | MMM DD, YYYY             | June 11, 2018             |
| Time only<br>Note - In this case, the command assumes the current date. | HH:MM:SS                 | 14:20:00                  |
| Date and Time                                                           | MMM DD, YYYY<br>HH:MM:SS | June 11, 2018<br>14:20:00 |

## Output

Each output line consists of a single log entry, whose fields appear in this format:

**Note** - The fields that show depends on the connection type.

```
HeaderDateHour ContentVersion HighLevelLogKey Uuid SequenceNum
Flags Action Origin IfDir InterfaceName LogId ...
```

This table describes some of the fields.

| Field Header    | Description         | Example                                   |
|-----------------|---------------------|-------------------------------------------|
| HeaderDateHour  | Date and Time       | 12Jun2018 12:56:42                        |
| ContentVersion  | Version             | 5                                         |
| HighLevelLogKey | High Level Log Key  | <max_null>, or empty                      |
| Uuid            | Log UUID            | (0x5b1f99cb, 0x0, 0x3403a8c0, 0xc0000000) |
| SequenceNum     | Log Sequence Number | 1                                         |

| Field Header | Description                                                                                                                                                                                      | Example                                                                                                                                                                                                                                       |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Flags        | Internal flags that specify the "nature" of the log - for example, control, audit, accounting, complementary, and so on                                                                          | 428292                                                                                                                                                                                                                                        |
| Action       | Action performed on this connection                                                                                                                                                              | <ul style="list-style-type: none"> <li>■ accept</li> <li>■ dropreject</li> <li>■ encrypt</li> <li>■ decrypt</li> <li>■ vpnroute</li> <li>■ keyinst</li> <li>■ authorize</li> <li>■ deauthorize</li> <li>■ authcrypt</li> <li>■ ctl</li> </ul> |

| ProductFamily | Name of the Check Point product family that generated this log   | Network                                                                                                                          |

## Examples

### Example 1 - Show all log entries with both the date and the time for each log entry

```
fw log -l
```

### Example 2 - Show all log entries that start after the specified timestamp

```
[Expert@MyGW:0]# fw log -l -s "June 12, 2018 12:33:00"
12Jun2018 12:33:00 5 N/A 1 accept MyGW > N/A LogId: <max_null>; ContextNum: <max_null>; OriginSicName: CN=MyGW,O=MyDomain_
Server.checkpoint.com.s6t98x; fg-1_client_in_rule_name: Default; fg-1_client_out_rule_name: Default; fg-1_server_in_rule_name: Host
Redirect; fg-1_server_out_rule_name: ; ProductName: FG; ProductFamily: Network;

12Jun2018 12:33:39 5 N/A 1 drop MyGW < eth0 LogId: 0; ContextNum: <max_null>; OriginSicName: CN=MyGW,O=MyDomain_
Server.checkpoint.com.s6t98x; inzone: Local; outzone: External; service_id: ftp; src: MyGW; dst: MyFTPServer; proto: tcp; UP_match_
table: TABLE_START; ROW_START: 0; match_id: 2; layer_uuid: 4e26fc30-b345-4c96-b8d7-9db6aa7cdd89; layer_name: MyPolicy Network; rule_
uid: 802020d9-5cdc-4c74-8e92-47e1b0eb72e5; rule_name: ; ROW_END: 0; UP_match_table: TABLE_END; UP_action_table: TABLE_START; ROW_

ProductFamily: Network;
[Expert@MyGW:0]#
```

### Example 5 - Show all log entries with action "drop", show all field headers, and show log flags

```
[Expert@MyGW:0]# fw log -l -q -w -c drop
HeaderDateHour: 12Jun2018 12:33:39; ContentVersion: 5; HighLevelLogKey: <max_null>; LogUid: ; SequenceNum: 1; Flags: 428292; Action:
drop; Origin: MyGW; IfDir: <; InterfaceName: eth0; Alert: ; LogId: 0; ContextNum: <max_null>; OriginSicName: CN=MyGW,O=MyDomain_
Server.checkpoint.com.s6t98x; inzone: Local; outzone: External; service_id: ftp; src: MyGW; dst: MyFTPServer; proto: tcp; UP_match_
table: TABLE_START; ROW_START: 0; match_id: 2; layer_uuid: 4e26fc30-b345-4c96-b8d7-9db6aa7cdd89; layer_name: MyPolicy Network; rule_
uid: 802020d9-5cdc-4c74-8e92-47e1b0eb72e5; rule_name: ; ROW_END: 0; UP_match_table: TABLE_END; UP_action_table: TABLE_START; ROW_
START: 0; action: 0; ROW_END: 0; UP_action_table: TABLE_END; ProductName: VPN-1 & FireWall-1; svc: ftp; sport_svc: 64933;
ProductFamily: Network;
[Expert@MyGW:0]#
```

### Example 6 - Show only log entries from 0 to 10 (counting from the beginning of the log file)

```
[Expert@MyGW:0]# fw log -l -x 0 -y 10
... ..
[Expert@MyGW:0]#
```

# fw logswitch

## Description

Switches the current active log file:

1. Closes the current active log file.
2. Renames the current active log file.
3. Creates a new active log file with the default name.

### Notes:

- By default, this command switches the active Security log file - `$FWDIR/log/fw.log`
- You can specify to switch the active Audit log file - `$FWDIR/log/fw.adtlog`

**Important** You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).

## Syntax

```
fw [-d] logswitch
    [-audit] [<Name of Switched Log>]
    -h <Target> [[+ | -]<Name of Switched Log>]
```

## Parameters

| Parameter | Description                                                                                                                                                                                                                                                                                                                                |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d        | Runs the command in debug mode.<br>Use only if you troubleshoot the command itself.<br> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session. |
| -audit    | Specifies to switch the active Audit log file ( <code>\$FWDIR/log/fw.adtlog</code> ).<br>You can use this parameter only on a Management Server.                                                                                                                                                                                           |

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -         | <p>Specifies to <i>transfer</i> the active log from the remote server to the local server.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>■ The command saves the copied active log file in the <code>\$FWDIR/log/</code> directory on the local server and then deletes the switched log file on the remote server.</li> <li>■ If you specify the name of the switched log file, you must write it immediately after this - (minus) parameter.</li> <li>■ The default name of the saved log file is:<br/> <code>&lt;Gateway_Object_Name&gt;__&lt;YYYY-MM-DD_HHMMSS&gt;.log</code><br/> For example, <code>MyGW__2018-03-26_174455.log</code></li> <li>■ If you specify the name of the switched log file, then the name of the saved log file is:<br/> <code>&lt;Gateway_Object_Name&gt;__&lt;Specified_Log_Name&gt;.log</code></li> <li>■ When this command transfers the log file from the remote server, it compresses the file.</li> <li>■ As an alternative, you can use the <a href="#">"fw fetchlogs" on page 268</a> command.</li> </ul> |

## Compression

When this command transfers the log files from the remote server, it compresses the file with the `gzip` command (see RFC 1950 to RFC 1952 for details). The algorithm is a variation of LZ77 method. The compression ratio varies with the content of the log file and is difficult to predict. Binary data are not compressed. Text data, such as user names and URLs, are compressed.

### Example - Switching the active Security log on a Security Management Server or Security Gateway

```
[Expert@MGMT:0]# fw logswitch
Log file has been switched to: 2018-06-13_182359.log
[Expert@MGMT:0]#
```

### Example - Switching the active Audit log on a Security Management Server

```
[Expert@MGMT:0]# fw logswitch -audit
Log file has been switched to: 2018-06-13_185711.adtlog
[Expert@MGMT:0]#
```

**Example - Switching the active Security log on a managed Security Gateway and copying the switched log**

```
[Expert@MGMT:0]# fw logswitch -h MyGW +
Log file has been switched to: 2018-06-13_185451.log
[Expert@MGMT:0]#
[Expert@MGMT:0]# ls $FWDIR/log/*.log
/opt/CPsuite-R82.10/fw1/log/fw.log
/opt/CPsuite-R82.10/fw1/log/MyGW__2018-06-13_185451.log
[Expert@MGMT:0]#

[Expert@MyGW:0]# ls $FWDIR/log/*.log
/opt/CPsuite-R82.10/fw1/log/fw.log
/opt/CPsuite-R82.10/fw1/log/2018-06-13_185451.log
[Expert@MyGW:0]#
```

# fw lslogs

## Description

Shows a list of Security log files (`$FWDIR/log/*.log`) and Audit log files (`$FWDIR/log/*.adtlog`) residing on the local server or a remote server.

 **Important** - You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).

## Syntax

```
fw [-d] lslogs [-f <Name of Log File 1>] [-f <Name of Log File 2>]
... [-f <Name of Log File N>] [-e] [-r] [-s {name | size | stime |
etime}] [<Target>]
```

## Parameters

| Parameter                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-d</code>                          | <p>Runs the command in debug mode.<br/>Use only if you troubleshoot the command itself.</p> <p> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p>                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>-f &lt;Name of Log File&gt;</code> | <p>Specifies the name of the log file to show.<br/>Need to specify only the name.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>■ If the log file name is not specified explicitly, the command shows all Security log files (<code>\$FWDIR/log/*.log</code>).</li> <li>■ File names may include <code>*</code> and <code>?</code> as wildcards (for example, <code>2019-0?-*</code>).<br/>If you enter a wildcard, you must enclose it in double quotes or single quotes.</li> <li>■ You can specify multiple log files in one command.<br/>You must use the <code>-f</code> parameter for each log file name pattern:<br/> <pre>-f &lt;Name of Log File 1&gt; -f &lt;Name of Log File 2&gt; ... -f &lt;Name of Log File N&gt;</pre> </li> </ul> |

| Parameter                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-e</code>                               | Shows an extended file list. It includes the following information for each log file: <ul style="list-style-type: none"> <li>■ <code>Size</code> - The total size of the log file and its related pointer files</li> <li>■ <code>Creation Time</code> - The time the log file was created</li> <li>■ <code>Closing Time</code> - The time the log file was closed</li> <li>■ <code>Log File Name</code> - The file name</li> </ul>                                                                                                                                                                                                                              |
| <code>-r</code>                               | Reverses the sort order (descending order).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>-s {name   size   stime   etime}</code> | Specifies the sort order of the log files using one of the following sort options: <ul style="list-style-type: none"> <li>■ <code>name</code> - The file name</li> <li>■ <code>size</code> - The file size</li> <li>■ <code>stime</code> - The time the log file was created (this is the default option)</li> <li>■ <code>etime</code> - The time the log file was closed</li> </ul>                                                                                                                                                                                                                                                                           |
| <code>&lt;Target&gt;</code>                   | Specifies the remote Check Point server, with which this local Check Point server has established SIC trust. <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>■ The local and the remote servers must have established SIC trust.</li> <li>■ The local server can be a Security Management Server, a Log Server, a Security Gateway, a Cluster Member.</li> <li>■ The remote server can be a Security Gateway, a Cluster Member, a Log Server, or a Security Management Server in High Availability deployment.</li> <li>■ You can specify the remote managed server by its main IP address or Object Name as configured in SmartConsole.</li> </ul> |

### Example 1 - Default output

```
[Expert@HostName:0]# fw lslogs
  Size Log file name
    9KB 2019-06-14_000000.log
   11KB 2019-06-15_000000.log
    9KB 2019-06-16_000000.log
   10KB 2019-06-17_000000.log
    9KB fw.log
[Expert@HostName:0]#
```

**Example 2 - Showing all log files**

```
[Expert@HostName:0]# fw lslogs -f ""
Size Log file name
9KB fw.adtlog
9KB fw.log
9KB 2019-05-29_000000.adtlog
9KB 2019-05-29_000000.log
9KB 2019-05-20_000000.adtlog
9KB 2019-05-20_000000.log
[Expert@HostName:0]#
```

**Example 3 - Showing only log files specified by the patterns**

```
[Expert@HostName:0]# fw lslogs -f "2019-06-14*" -f '2019-06-15*'
Size Log file name
9KB 2019-06-14_000000.adtlog
9KB 2019-06-14_000000.log
11KB 2019-06-15_000000.adtlog
11KB 2019-06-15_000000.log
[Expert@HostName:0]#
```

**Example 4 - Showing only log files specified by the patterns and their extended information**

```
[Expert@HostName:0]# fw lslogs -f "2019-06-14*" -f '2019-06-15*'
Size Log file name
9KB 2019-06-14_000000.adtlog
9KB 2019-06-14_000000.log

[Expert@MGMT:0]#
```

# fw mergefiles

## Description

Merges several Security log files (`$FWDIR/log/*.log`) into a single log file.

Merges several Audit log files (`$FWDIR/log/*.adtlog`) into a single log file.

### Important:

- Do not merge the *active* Security file `$FWDIR/log/fw.log` with other Security switched log files.  
Switch the active Security file `$FWDIR/log/fw.log` (with the "[fw logswitch](#)" on [page 1177](#) command) and only then merge it with other Security switched log files.
- Do not merge the *active* Audit file `$FWDIR/log/fw.adtlog` with other Audit switched log files.  
Switch the active Audit file `$FWDIR/log/fw.adtlog` (with the "[fw logswitch](#)" on [page 1177](#) command) and only then merge it with other Audit switched log files.
- This command unifies logs entries with the same Unique-ID (UID). If you rotate the current active log file before all the segments of a specific log arrive, this command merges the records with the same Unique ID from two different files, into one fully detailed record.
- If the size of the final merged log file exceeds 2GB, this command creates a list of merged files, where the size of each merged file size is not more than 2GB.  
The user receives this warning:

```
Warning: The size of the files you have chosen to merge
is greater than 2GB. The merge will produce two or more
files.
```

The names of merged files are:

- `<Name of Merged Log File>.log`
- `<Name of Merged Log File>_1.log`
- `<Name of Merged Log File>_2.log`
- ...
- `<Name of Merged Log File>_N.log`

-  **Important** - You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).

## Syntax

```
fw [-d] mergefiles {-h | -help}
```

```
fw [-d] mergefiles [-r] [-s] [-t <Time Conversion File>] <Name of
Log File 1> <Name of Log File 2> ... <Name of Log File N> <Name of
Merged Log File>
```

## Parameters

| Parameter                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d                        | <p>Runs the command in debug mode.<br/>Use only if you troubleshoot the command itself.</p> <p> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p>                                                                                                                                                                                                                                                                                                                                                                 |
| {-h   -help}              | Shows the built-in usage.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| -r                        | Removes duplicate entries.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| -s                        | Sorts the merged file by the <b>Time</b> field in log records.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| -t <Time Conversion File> | <p>Specifies a full path and name of a file that instructs this command how to adjust the times during the merge. This is required if you merge log files from Log Servers configured with different time zones.<br/>The file format is:</p> <pre>&lt;IP Address of Log Server #1&gt; &lt;Signed Date Time #1 in Seconds&gt; &lt;IP Address of Log Server #2&gt; &lt;Signed Date Time #2 in Seconds&gt; ... ..</pre> <p> <b>Notes</b></p> <ul style="list-style-type: none"> <li>■ You must specify the absolute path and the file name.</li> <li>■ The name of the time conversion file cannot exceed 230 characters.</li> </ul> |

| Parameter                                                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <p><i>&lt;Name of Log File 1&gt;</i><br/> <i>... &lt;Name of Log File N&gt;</i></p> | <p>Specifies the log files to merge.</p> <p> <b>Notes:</b></p> <ul style="list-style-type: none"> <li>■ You must specify the absolute path and the name of the input log files.</li> <li>■ The name of the input log file cannot exceed 230 characters.</li> </ul>                                                                                                                                                                                                                                          |
| <p><i>&lt;Name of Merged Log File&gt;</i></p>                                       | <p>Specifies the output merged log file.</p> <p> <b>Notes:</b></p> <ul style="list-style-type: none"> <li>■ The name of the merged log file cannot exceed 230 characters.</li> <li>■ If a file with the specified name already exists, the command stops and asks you to remove the existing file, or to specify another name.</li> <li>■ The size of the merged log file cannot exceed 2 GB. In such scenario, the command creates several merged log files, each not exceeding the size limit.</li> </ul> |

### Example - Merging Security log files

```
[Expert@HostName:0]# ls -l $FWDIR/*.log
-rw-rw-r-- 1 admin root 189497 Sep  7 00:00 2019-09-07_000000.log

# fw monitor

## Description

Firewall Monitor is the Check Point traffic capture tool.

In a Security Gateway, traffic passes through different inspection points - Chain Modules in the Inbound direction and then in the Outbound direction (see ["fw ctl chain" on page 1113](#)).

The FW Monitor tool captures the traffic at each Chain Module in both directions.

You can later analyze the captured traffic with the same FW Monitor tool, or with special tools like Wireshark.

### Notes:

- Only one instance of "fw monitor" can run at a time.
- You can stop the "fw monitor" instance in one of these ways:
  - In the shell, in which the "fw monitor" instance runs, press **CTRL + C** keys
  - In another shell, run this command: `fw monitor -U`
- Each time you run the FW Monitor, it compiles its temporary policy files (`$FWDIR/tmp/monitorfilter.*`).
- The FW Monitor also show the traffic accelerated with SecureXL.
- For more information, see [sk30583](#).
- Also, refer to ["cpmonitor" on page 1019](#) and ["cppcap" on page 1021](#).

### Important:

- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- On Scalable Platforms, you must connect to the applicable Security Group.

## Syntax for IPv4

```
fw monitor {-h | -help}
```

```
fw monitor [-d] [-D] [-ci <Number of Inbound Packets>] [-co
<Number of Outbound Packets>] [-e <INSPECT Expression> | -f
{<INSPECT Filter File> | -}] [-F "<Source IP>,<Source Port>,<Dest
IP>,<Dest Port>,<Protocol Number>"] [-H "<IP Address>"] [-i] [-l
<Length>] [-m {i,I,o,O,e,E}] [-o <Output File> [-w]] [[-pi
<Position>] [-pI <Position>] [-po <Position>] [-pO <Position>] | -
p all [-a]] [-T] [-u | -s] [-U] [-v <VSID>] [-x <Offset>
[,<Length>] [-w]] [-b <Size of Buffer>]
```

## Syntax for IPv6

```
fw6 monitor {-h | -help}
```

```
fw6 monitor [-d] [-D] [-ci <Number of Inbound Packets>] [-co
<Number of Outbound Packets>] [-e <INSPECT Expression> | -f
{<INSPECT Filter File> | -}] [-F "<Source IP>,<Source Port>,<Dest
IP>,<Dest Port>,<Protocol Number>"] [-H "<IP Address>"] [-i] [-l
<Length>] [-m {i,I,o,O,e,E}] [-o <Output File> [-w]] [[-pi
<Position>] [-pI <Position>] [-po <Position>] [-pO <Position>] | -
p all [-a]] [-T] [-u | -s] [-U] [-v <VSID>] [-x <Offset>
[,<Length>] [-w]] [-b <Size of Buffer>]
```

## Parameters

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|---------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>-o &lt;Output File&gt;</pre>                                                                             | <p>Specifies the output file, to which FW Monitor writes the captured raw data.</p> <p> <b>Important</b> - If you do not specify the path explicitly, FW Monitor creates this output file in the current working directory. Because this output file can grow very fast to very large size, we always recommend to specify the full path to the largest partition <code>/var/log/</code>.</p> <p>The format of this output file is the same format used by tools like <code>snoop</code> (refer to <a href="#">RFC 1761</a>).</p> <p>You can later analyze the captured traffic with the same FW Monitor tool, or with special tools like Wireshark.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <pre>-pi &lt;Position&gt; -pI &lt;Position&gt; -po &lt;Position&gt; -pO &lt;Position&gt; or -p all [-a]</pre> | <p>Inserts the FW Monitor Chain Module at the specified position between the kernel Chain Modules (see the <a href="#">"fw ctl chain" on page 1113</a>).</p> <p>If the FW Monitor writes the captured data to the specified output file (with the parameter <code>"-o &lt;Output File&gt;"</code>), it also writes the position of the FW Monitor chain module as one of the fields. You can insert the FW Monitor Chain Module in these positions only:</p> <ul style="list-style-type: none"> <li>■ <code>-pi &lt;Position&gt;</code><br/>Inserts the FW Monitor Chain Module in the specified Pre-Inbound position.</li> <li>■ <code>-pI &lt;Position&gt;</code><br/>Inserts the FW Monitor Chain Module in the specified Post-Inbound position.</li> <li>■ <code>-po &lt;Position&gt;</code><br/>Inserts the FW Monitor Chain Module in the specified Pre-Outbound position.</li> <li>■ <code>-pO &lt;Position&gt;</code><br/>Inserts the FW Monitor Chain Module in the specified Post-Outbound position</li> <li>■ <code>-p all [-a]</code><br/>Inserts the FW Monitor Chain Module at all positions (both Inbound and Outbound).</li> </ul> <p> <b>Warning</b> - This parameter causes very high load on the CPU, but provides the most complete traffic capture.</p> <p>The <code>"-a"</code> parameter specifies to use absolute chain positions. This parameter changes the chain ID from a relative value (which only makes sense with the matching output from the <a href="#">"fw ctl chain" on page 1113</a> command) to an absolute value.</p> |

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           | <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>■ <i>&lt;Position&gt;</i> can be one of these: <ul style="list-style-type: none"> <li>• A relative position number<br/>In the output of the <i>"fw ctl chain" on page 1113</i> command, refer to the numbers in the leftmost column (for example, 0, 5, 14).</li> <li>• A relative position alias<br/>In the output of the <i>"fw ctl chain" on page 1113</i> command, refer to the internal chain module names in the rightmost column in the parentheses (for example, <code>sxl_in</code>, <code>fw</code>, <code>cpas</code>).</li> <li>• An absolute position<br/>In the output of the <i>"fw ctl chain" on page 1113</i> command, refer to the numbers in the second column from the left (for example, <code>-7ffffff</code>, <code>-1fffff8</code>, <code>7f730000</code>). In the syntax, you must write these numbers in the hexadecimal format (for example, <code>-0x7ffffff</code>, <code>-0x1fffff8</code>, <code>0x7f730000</code>).</li> </ul> </li> <li>■ You can use this chain module position parameter <code>"-p{i   I   o   O} ..."</code> together with the capture mask parameter <code>"-m {i, I, o, O, e, E}"</code>.</li> <li>■ In the inbound direction: <ul style="list-style-type: none"> <li>• All chain positions <i>before</i> the FireWall Virtual Machine module are Pre-Inbound (the <i>"fw ctl chain" on page 1113</i> command shows this module as <code>"fw VM inbound"</code>).</li> <li>• All chain modules <i>after</i> the FireWall Virtual Machine module are Post-Inbound.</li> </ul> </li> <li>■ In the outbound direction: <ul style="list-style-type: none"> <li>• All chain position <i>before</i> the FireWall Virtual Machine module are Pre-Outbound.</li> <li>• All chain modules <i>after</i> the FireWall Virtual Machine module are Post-Outbound.</li> </ul> </li> <li>■ By default, the FW Monitor captures the traffic only in the FireWall Virtual Machine module.</li> <li>■ The chain module position parameters <code>"-p{i   I   o   O} ..."</code> parameters do <b>not</b> apply to the accelerated traffic, which is still monitored at the default inbound and outbound positions.</li> <li>■ For more information about the inspection points, see the applicable table below.</li> </ul> |

| Parameter      | Description                                                                                                                                                                                                                                                                                                     |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -T             | <p>Shows the timestamp for each packet:<br/>DDMMYYYY HH:MM:SS.mmmmmm</p> <p>★ <b>Best Practice</b> - Use this parameter if you do not save the output to a file, but print it on the screen.</p>                                                                                                                |
| -u<br>or<br>-s | <p>Shows UUID for each packet (it is only possible to print either the UUID, or the SUUID - not both):</p> <ul style="list-style-type: none"> <li>■ -u<br/>Prints connection's Universal-Unique-ID (UUID) for each packet</li> <li>■ -s<br/>Prints connection's Session UUID (SUUID) for each packet</li> </ul> |
| -U             | <p>Removes the simple capture filters specified with this parameter:</p> <pre>-F "&lt;Source IP&gt;,&lt;Source Port&gt;,&lt;Dest IP&gt;,&lt;Dest Port&gt;,&lt;Protocol Number&gt;"</pre>                                                                                                                        |
| -v <VSID>      | <p>On a VSX Gateway or VSX Cluster Member, captures the packets on the specified Virtual System or Virtual Router.</p> <p>By default, FW Monitor captures the packets on all Virtual Systems and Virtual Routers.</p> <p>Example:</p> <pre>fw monitor -v 4 -e "accept;" -o /var/log/fw_mon.cap</pre>            |
| -w             | <p>Captures the entire packet, instead of only the header.</p> <p>Must be used together with one of these parameters:</p> <ul style="list-style-type: none"> <li>■ -o &lt;Output File&gt;</li> <li>■ -x &lt;Offset&gt;[,&lt;Length&gt;]</li> </ul>                                                              |

| Parameter                                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-x &lt;Offset&gt;</code><br><code>[,&lt;Length&gt;]</code> | <p>Specifies the position in each packet, where the FW Monitor starts to capture the data from each packet.</p> <p>Optionally, it is also possible to limit the amount of data the FW Monitor captures.</p> <ul style="list-style-type: none"> <li>■ <code>&lt;Offset&gt;</code><br/>Specifies how many bytes to skip from the beginning of each packet. FW Monitor starts to capture the data from each packet only after the specified number of bytes.</li> <li>■ <code>&lt;Length&gt;</code><br/>In versions lower than R82.10, the <code>fw monitor -x &lt;offset&gt;, &lt;val&gt;</code> command regards the second parameter ("<code>val</code>") as the end offset to be displayed. Starting in R82.10 it regards that value as the length in bytes to be displayed. For example, <code>fw monitor -x 12,28</code> previously printed the content of bytes 12-28 of the captured traffic. Starting in R82.10 it prints 28 bytes, (bytes 12-40).</li> </ul> |

### Inspection points in Security Gateway and in the FW Monitor output

**Note** - The Inbound and Outbound traffic direction relates to each specific packet, and not to the connection.

### ■ Inbound

| Name of inspection point | Relation to the FireWall Virtual Machine | Notion of inspection point in the FW Monitor output |
|--------------------------|------------------------------------------|-----------------------------------------------------|
| Pre-Inbound              | Before the inbound FireWall VM           | i (for example, eth4:i)                             |
| Post-Inbound             | After the inbound FireWall VM            | I (for example, eth4:I)                             |
| Pre-Inbound VPN          | Inbound before decrypt                   | id (for example, eth4:id)                           |
| Post-Inbound VPN         | Inbound after decrypt                    | ID (for example, eth4:ID)                           |
| Pre-Inbound QoS          | Inbound before QoS                       | iq (for example, eth4:iq)                           |
| Post-Inbound QoS         | Inbound after QoS                        | IQ (for example, eth4:IQ)                           |

### ■ Outbound

| Name of inspection point | Relation to the FireWall Virtual Machine | Notion of inspection point in the FW Monitor output |
|--------------------------|------------------------------------------|-----------------------------------------------------|
| Pre-Outbound             | Before the outbound FireWall VM          | o (for example, eth4:o)                             |
| Post-Outbound            | After the outbound FireWall VM           | O (for example, eth4:O)                             |
| Pre-Outbound VPN         | Outbound before encrypt                  | e (for example, eth4:e)                             |
| Post-Outbound VPN        | Outbound after encrypt                   | E (for example, eth4:E)                             |
| Pre-Outbound QoS         | Outbound before QoS                      | oq (for example, eth4:oq)                           |
| Post-Outbound QoS        | Outbound after QoS                       | OQ (for example, eth4:OQ)                           |

## Generic Examples

### Example 1 - Default syntax

```
[Expert@MyGW:0]# fw monitor
monitor: getting filter (from command line)
monitor: compiling
monitorfilter:
Compiled OK.
monitor: loading
monitor: monitoring (control-C to stop)
[vs_0][fw_1] eth0:i[40]: 192.168.204.1 -> 192.168.204.40 (TCP) len=40 id=31789
TCP: 53901 -> 22 ....A. seq=761113cd ack=f92e2a13
[vs_0][fw_1] eth0:I[40]: 192.168.204.1 -> 192.168.204.40 (TCP) len=40 id=31789
TCP: 53901 -> 22 ....A. seq=761113cd ack=f92e2a13
[vs_0][fw_1] eth0:i[40]: 192.168.204.1 -> 192.168.204.40 (TCP) len=40 id=31790
TCP: 53901 -> 22 ....A. seq=761113cd ack=f92e2a47
... ..
monitor: caught sig 2
monitor: unloading
[Expert@MyGW:0]#
```

### Example 2 - Showing timestamps in the output for each packet

```
[Expert@MyGW:0]# fw monitor -T
monitor: getting filter (from command line)
monitor: compiling
monitorfilter:
Compiled OK.
monitor: loading
monitor: monitoring (control-C to stop)
[vs_0][fw_1] 12Sep2018 19:08:05.453947 eth0:oq[124]: 192.168.3.53 -> 172.20.168.16 (TCP)
len=124 id=38414

[Expert@MyGW:0]#
```

## Examples for the "-e" parameter

### Example 1 - Capture everything

```
[Expert@HostName]# fw monitor -e "accept;" -o /var/log/fw_mon.cap
```

### Example 2 - Capture traffic to / from specific hosts

To specify a host, you can use one of these expressions:

- Use "host (<IP\_Address\_in\_Doted\_Decimal\_format>)", which applies to both Source IP address and Destination IP address
- Use a specific Source IP address "src=<IP\_Address\_in\_Doted\_Decimal\_format>" and a specific Destination IP address "dst=<IP\_Address\_in\_Doted\_Decimal\_format>"

Example filters:

- Capture everything between host X and host Y:

```
[Expert@HostName]# fw monitor -e "host(x.x.x.x) and host
(y.y.y.y), accept;" -o /var/log/fw_mon.cap
```

```
[Expert@HostName]# fw monitor -e "((src=x.x.x.x ,
dst=y.y.y.y) or (src=y.y.y.y , dst=x.x.x.x)), accept;" -o
/var/log/fw_mon.cap
```

- Capture everything between hosts X,Z and hosts Y,Z in *all* Firewall kernel chains:

```
[Expert@HostName]# fw monitor -p all -e "((src=x.x.x.x or
dst=z.z.z.z) and (src=y.y.y.y or dst=z.z.z.z)), accept ;" -o
/var/log/fw_mon.cap
```

- Capture everything to/from host X or to/from host Y or to/from host Z:

```
[Expert@HostName]# fw monitor -e "host(x.x.x.x) or host
(y.y.y.y) or host(z.z.z.z), accept;" -o /var/log/fw_mon.cap
```

```
[Expert@HostName]# fw monitor -e "((src=x.x.x.x or
dst=x.x.x.x) or (src=y.y.y.y or dst=y.y.y.y) or (src=z.z.z.z
or dst=z.z.z.z)), accept;" -o /var/log/fw_mon.cap
```

### Example 3 - Capture traffic to / from specific ports

 **Note** - You must specify port numbers in Decimal format. Refer to the `/etc/services` file on the Security Gateway, or to [IANA Service Name and Port Number Registry](#).

To specify a port, you can use one of these expressions:

- Use `"port(<IANA_Port_Number>)"`, which applies to both Source Port and Destination Port
- Use a specific Source Port `"sport=<IANA_Port_Number>"` and a specific Destination Port `"dport=<IANA_Port_Number>"`
- In addition:
  - For specific TCP port, you can use `"tcpport(<IANA_Port_Number>)"`, which applies to both Source TCP Port and Destination TCP Port
  - For specific UDP port, you can use `"udpport(<IANA_Port_Number>)"`, which applies to both Source UDP Port and Destination UDP Port

Example filters:

- Capture everything to/from port X:

```
[Expert@HostName]# fw monitor -e "port(x), accept;" -o /var/log/fw_mon.cap
```

```
[Expert@HostName]# fw monitor -e "(sport=x or dport=x), accept;" -o /var/log/fw_mon.cap
```

- Capture everything except port X:

```
[Expert@HostName]# fw monitor -e "((sport!=x) or (dport!=x)), accept;" -o /var/log/fw_mon.cap
```

```
[Expert@HostName]# fw monitor -e "not (sport=x or dport=x), accept;" -o /var/log/fw_mon.cap
```

- Capture everything except SSH:

```
[Expert@HostName]# fw monitor -e "((sport!=22) or (dport!=22)), accept;" -o /var/log/fw_mon.cap
```

```
[Expert@HostName]# fw monitor -e "not (sport=22 or dport=22), accept;" -o /var/log/fw_mon.cap
```

```
[Expert@HostName]# fw monitor -e "not tcpport(22), accept;" -o /var/log/fw_mon.cap
```

- Capture everything to/from host X except SSH:

```
[Expert@HostName]# fw monitor -e "(host(x.x.x.x) and (sport!=22 or dport!=22)), accept;" -o /var/log/fw_mon.cap
```

```
[Expert@HostName]# fw monitor -e "((src=x.x.x.x or dst=x.x.x.x) and (not (sport=22 or dport=22))), accept;" -o /var/log/fw_mon.cap
```

```
[Expert@HostName]# fw monitor -e "(host(x.x.x.x) and not tcpport(22)), accept;" -o /var/log/fw_mon.cap
```

- Capture everything except NTP:

```
[Expert@HostName]# fw monitor -e "not udpport(123), accept;" -o /var/log/fw_mon.cap
```

#### Example 4 - Capture traffic over specific protocol

 **Note** - You must specify protocol numbers in Decimal format. Refer to the `/etc/protocols` file on the Security Gateway, or to [IANA Protocol Numbers](#).

To specify a protocol, you can use one of these expressions:

- Use `"ip_p=<IANA_Protocol_Number>"`

*Examples:*

- To specify TCP protocol with byte offset, use `"ip_p=6"`
- To specify UDP protocol with byte offset, use `"ip_p=11"`
- To specify ICMP protocol with byte offset, use `"ip_p=1"`

- Use `"accept [9:1]=<IANA_Protocol_Number>"`

*Examples:*

- To specify TCP protocol with byte offset, use `"accept [9:1]=6"`
- To specify UDP protocol with byte offset, use `"accept [9:1]=11"`
- To specify ICMP protocol with byte offset, use `"accept [9:1]=1"`

- In addition, you can explicitly use these expressions to specify protocols:

**Summary Table**

| Which protocol to specify | On which port(s) traffic is captured | Expression                                                          |
|---------------------------|--------------------------------------|---------------------------------------------------------------------|
| TCP                       | N/A                                  | <code>"tcp, accept;"</code>                                         |
| UDP                       | N/A                                  | <code>"udp, accept;"</code>                                         |
| ICMPv4                    | N/A                                  | <code>"icmp, accept;"</code><br>or<br><code>"icmp4, accept;"</code> |
| ICMPv6                    | N/A                                  | <code>"icmp6, accept;"</code>                                       |
| HTTP                      | TCP 80                               | <code>"http, accept;"</code>                                        |
| HTTPS                     | TCP 443                              | <code>"https, accept;"</code>                                       |
| PROXY                     | TCP 8080                             | <code>"proxy, accept;"</code>                                       |
| DNS                       | UDP 53                               | <code>"dns, accept;"</code>                                         |
| IKE                       | UDP 500                              | <code>"ike, accept;"</code>                                         |
| NAT-T                     | UDP 4500                             | <code>"natt, accept;"</code>                                        |
| ESP and IKE               | IP proto 50 and UDP 500              | <code>"vpn, accept;"</code>                                         |

| Which protocol to specify                                                                                                                                                               | On which port(s) traffic is captured                                                                                                                                                          | Expression        |

| SMTP                                                                                                                                                                                    | TCP 25                                                                                                                                                                                        | "smtp, accept;"   |
| POP3                                                                                                                                                                                    | TCP 110                                                                                                                                                                                       | "pop3, accept;"   |

Example filters:

- Filter to capture everything on protocol X:

```
[Expert@HostName]# fw monitor -e "ip_p=X, accept;" -o /var/log/fw_mon.cap
```

- Filter to capture everything on protocol X and port Z on protocol Y:

```
[Expert@HostName]# fw monitor -e "(ip_p=X) or (ip_p=Y, port (Z)), accept;" -o /var/log/fw_mon.cap
```

- Filter to capture everything TCP between host X and host Y:

```
[Expert@HostName]# fw monitor -e "ip_p=6, host(x.x.x.x) or host(y.y.y.y), accept;" -o /var/log/fw_mon.cap
```

```
[Expert@HostName]# fw monitor -e "tcp, host(x.x.x.x) or host(y.y.y.y), accept;" -o /var/log/fw_mon.cap
```

```
[Expert@HostName]# fw monitor -e "accept [9:1]=6 , ((src=x.x.x.x , dst=y.y.y.y) or (src=y.y.y.y , dst=x.x.x.x));"
```

```
[Expert@HostName]# fw monitor -e "ip_p=6, ((src=x.x.x.x , dst=y.y.y.y) or (src=y.y.y.y , dst=x.x.x.x)), accept;" -o /var/log/fw_mon.cap
```

### Example 5 - Capture traffic with specific protocol options

**Note** - Refer to the `$FWDIR/lib/tcpip.def` file on Security Gateway.

### Summary Table for IPv4

| Option Description                          | Expression                                    | Example                                                      |
|---------------------------------------------|-----------------------------------------------|--------------------------------------------------------------|
| Source IPv4 address of the IPv4 packet      | <code>ip_src = &lt;IPv4_Address&gt;</code>    | <code>fw monitor -e "ip_src = 192.168.22.33, accept;"</code> |
| Destination IPv4 address of the IPv4 packet | <code>ip_dst = &lt;IPv4_Address&gt;</code>    | <code>fw monitor -e "ip_dst = 192.168.22.33, accept;"</code> |
| Time To Live of the IPv4 packet             | <code>ip_ttl = &lt;Number&gt;</code>          | <code>fw monitor -e "ip_ttl = 255, accept;"</code>           |
| Total Length of the IPv4 packet in bytes    | <code>ip_len = &lt;Length_in_Bytes&gt;</code> | <code>fw monitor -e "ip_len = 64, accept;"</code>            |

| Option Description                                                             | Expression                                       | Example                                                                                                                                                                                                                                                                                                              |
|--------------------------------------------------------------------------------|--------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TOS field of the IPv4 packet                                                   | <code>ip_tos = &lt;Number&gt;</code>             | <code>fw monitor -e "ip_tos = 0, accept;"</code>                                                                                                                                                                                                                                                                     |
| IANA Protocol Number (either in Dec or in Hex) encapsulated in the IPv4 packet | <code>ip_p = &lt;IANA_Protocol_Number&gt;</code> | <p><b>Example for TCP:</b><br/> <code>fw monitor -e "ip_p = 6, accept;"</code></p> <p><b>Examples for UDP:</b><br/> <code>fw monitor -e "ip_p = 17, accept;"</code><br/> <code>fw monitor -e "ip_p = 0x11, accept;"</code></p> <p><b>Example for ICMPv4:</b><br/> <code>fw monitor -e "ip_p = 1, accept;"</code></p> |

Summary Table for IPv6

| Option Description                                                 | Expression                                        | Example                                                                   |
|--------------------------------------------------------------------|---------------------------------------------------|---------------------------------------------------------------------------|
| Source IPv6 address of the IPv6 packet                             | <code>ip_src6p = &lt;IPv6_Address&gt;</code>      | <code>fw monitor -e "ip_src6p = 0:0:0:0:0:ffff:c0a8:1621, accept;"</code> |
| Destination IPv6 address of the IPv6 packet                        | <code>ip_dst6p = &lt;IPv6_Address&gt;</code>      | <code>fw monitor -e "ip_dst6p = 0:0:0:0:0:ffff:c0a8:1621, accept;"</code> |
| Payload Length of the IPv6 packet in bytes                         | <code>ip_len6 = &lt;Length_in_Bytes&gt;</code>    | <code>fw monitor -e "ip_len6 = 1000, accept;"</code>                      |
| Hop Limit ("Time To Live") of the IPv6 packet                      | <code>ip_ttl6 = &lt;Number&gt;</code>             | <code>fw monitor -e "ip_ttl6 = 255, accept;"</code>                       |
| Next Header of the IPv6 packet - encapsulated IANA Protocol Number | <code>ip_p6 = &lt;IANA_Protocol_Number&gt;</code> | <code>fw monitor -e "ip_p6 = 6, accept;"</code>                           |

Summary Table for TCP

| Option Description                                                                           | Expression  | Example                                        |
|----------------------------------------------------------------------------------------------|-------------|------------------------------------------------|
| SYN flag is set in TCP packet                                                                | syn         | fw monitor -e "ip_p = 6, syn, accept;"         |
| ACK flag is set in TCP packet                                                                | ack         | fw monitor -e "ip_p = 6, ack, accept;"         |
| RST flag is set in TCP packet                                                                | rst         | fw monitor -e "ip_p = 6, rst, accept;"         |
| FIN flag is set in TCP packet                                                                | fin         | fw monitor -e "ip_p = 6, fin, accept;"         |
| First packet of TCP connection<br>(SYN flag is set, but ACK flag is not set in TCP packet)   | first       | fw monitor -e "ip_p = 6, first, accept;"       |
| Not the first packet of TCP connection<br>(SYN flag is not set in TCP packet)                | not_first   | fw monitor -e "ip_p = 6, not_first, accept;"   |
| Established TCP connection<br>(either ACK flag is set, or SYN flag is not set in TCP packet) | established | fw monitor -e "ip_p = 6, established, accept;" |
| Last packet of TCP connection<br>(both ACK flag and FIN flag are set in TCP packet)          | last        | fw monitor -e "ip_p = 6, last, accept;"        |
| End of TCP connection<br>(either RST flag is set, or FIN flag is set in TCP packet)          | tcpdone     | fw monitor -e "ip_p = 6, tcpdone, accept;"     |

| Option Description                                   | Expression                                              | Example    |                                                               |
|------------------------------------------------------|---------------------------------------------------------|------------|---------------------------------------------------------------|
| General way to match the flags inside in TCP packets | <code>th_flags = &lt;Sum_of_Flags_Hex_Values&gt;</code> | TCP Flag   | Example                                                       |
|                                                      |                                                         | SYN (0x2)  | <code>fw monitor<br/>-e "th_flags = 0x2,<br/>accept;"</code>  |
|                                                      |                                                         | ACK (0x10) | <code>fw monitor<br/>-e "th_flags = 0x10,<br/>accept;"</code> |
|                                                      |                                                         | PSH (0x8)  | <code>fw monitor<br/>-e "th_flags = 0x8,<br/>accept;"</code>  |
|                                                      |                                                         | FIN (0x1)  | <code>fw monitor<br/>-e "th_flags = 0x1,<br/>accept;"</code>  |
|                                                      |                                                         | RST (0x4)  | <code>fw monitor<br/>-e "th_flags = 0x4,<br/>accept;"</code>  |
|                                                      |                                                         | URG (0x20) | <code>fw monitor<br/>-e "th_flags = 0x20,<br/>accept;"</code> |

| Option Description                            | Expression               | Example                                                                                                                                            |                                             |
|-----------------------------------------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------|
|                                               |                          | TCP Flag                                                                                                                                           | Example                                     |
|                                               |                          | SYN + ACK                                                                                                                                          | fw monitor<br>-e "th_flags = 0x12, accept;" |
|                                               |                          | PSH + ACK                                                                                                                                          | fw monitor<br>-e "th_flags = 0x18, accept;" |
|                                               |                          | FIN + ACK                                                                                                                                          | fw monitor<br>-e "th_flags = 0x11, accept;" |
|                                               |                          | RST + ACK                                                                                                                                          | fw monitor<br>-e "th_flags = 0x14, accept;" |
| TCP source port                               | th_sport = <Port_Number> | fw monitor -e "th_sport = 59259, accept;"                                                                                                          |                                             |
| TCP destination port                          | th_dport = <Port_Number> | fw monitor -e "th_dport = 22, accept;"                                                                                                             |                                             |
| TCP sequence number (either in Dec or in Hex) | th_seq = <Number>        | Example for Dec format:<br>fw monitor -e "th_seq = 3937833514, accept;"<br>Example for Hex format:<br>fw monitor -e "th_seq = 0xeab6922a, accept;" |                                             |

| Option Description                                | Expression                           | Example                                                                                                                                                                                    |

| TCP acknowledged number (either in Dec or in Hex) | <code>th_ack = &lt;Number&gt;</code> | <p><b>Example for Dec format:</b></p> <pre>fw monitor -e "th_ack = 509054325, accept;"</pre> <p><b>Example for Hex format:</b></p> <pre>fw monitor -e "th_ack = 0x1e578d75, accept;"</pre> |

### Summary Table for UDP

| Option Description   | Expression                                   | Example                                             |
|----------------------|----------------------------------------------|-----------------------------------------------------|
| UDP source port      | <code>uh_sport = &lt;Port_ Number&gt;</code> | <code>fw monitor -e "uh_sport = 53, accept;"</code> |
| UDP destination port | <code>uh_dport = &lt;Port_ Number&gt;</code> | <code>fw monitor -e "uh_dport = 53, accept;"</code> |

### Summary Table for ICMPv4

| Option Description                                | Expression                              | Example                                               |
|---------------------------------------------------|-----------------------------------------|-------------------------------------------------------|
| ICMPv4 packets with specified Type                | <code>icmp_type = &lt;Number&gt;</code> | <code>fw monitor -e "icmp_type = 0, accept;"</code>   |
| ICMPv4 packets with specified Code                | <code>icmp_code = &lt;Number&gt;</code> | <code>fw monitor -e "icmp_code = 0, accept;"</code>   |
| ICMPv4 packets with specified Identifier          | <code>icmp_id = &lt;Number&gt;</code>   | <code>fw monitor -e "icmp_id = 20583, accept;"</code> |
| ICMPv4 packets with specified Sequence number     | <code>icmp_seq = &lt;Number&gt;</code>  | <code>fw monitor -e "icmp_seq = 1, accept;"</code>    |
| ICMPv4 Echo Request packets (Type 8, Code 0)      | <code>echo_req</code>                   | <code>fw monitor -e "echo_req, accept;"</code>        |
| ICMPv4 Echo Reply packets (Type 0, Code 0)        | <code>echo_reply</code>                 | <code>fw monitor -e "echo_reply, accept;"</code>      |
| ICMPv4 Echo Request and ICMPv4 Echo Reply packets | <code>ping</code>                       | <code>fw monitor -e "ping, accept;"</code>            |

| Option Description                                                                                                             | Expression             | Example                                   |
|--------------------------------------------------------------------------------------------------------------------------------|------------------------|-------------------------------------------|
| Traceroute packets as implemented in Unix OS (UDP packets on ports above 30000 and with TTL<30; or ICMP Time exceeded packets) | traceroute             | fw monitor -e "traceroute, accept;"       |
| Traceroute packets as implemented in Windows OS (ICMP Request packets with TTL<30; or ICMP Time exceeded packets)              | tracert                | fw monitor -e "tracert, accept;"          |
| Length of ICMPv4 packets                                                                                                       | icmp_ip_len = <length> | fw monitor -e "icmp_ip_len = 84, accept;" |

Summary Table for ICMPv6

| Option Description                 | Expression            | Example                                 |
|------------------------------------|-----------------------|-----------------------------------------|
| ICMPv6 packets with specified Type | icmp6_type = <Number> | fw monitor -e "icmp6_type = 1, accept;" |
| ICMPv6 packets with specified Code | icmp6_code = <Number> | fw monitor -e "icmp6_code = 3, accept;" |

**Example 6 - Capture specific bytes in packets**

Syntax:

```
fw monitor -e "accept [ <Offset> : <Length> , <Byte Order> ]
<Relational-Operator> <Value>;"
```

Parameters:

| Parameter | Explanation                                                                                          |
|-----------|------------------------------------------------------------------------------------------------------|
| <Offset>  | Specifies the offset relative to the beginning of the IP packet from where the value should be read. |

| Parameter                          | Explanation                                                                                                                                                                                                                                                                                                                                 |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>&lt;Length&gt;</i>              | <p>Specifies the number of bytes:</p> <ul style="list-style-type: none"> <li>▪ 1 = byte</li> <li>▪ 2 = word</li> <li>▪ 4 = dword</li> </ul> <p>If length is not specified, FW Monitor assumes 4 (dword).</p>                                                                                                                                |
| <i>&lt;Byte Order&gt;</i>          | <p>Specifies the byte order:</p> <ul style="list-style-type: none"> <li>▪ b = big endian, or network order</li> <li>▪ l = little endian, or host order</li> </ul> <p>If order is not specified, FW Monitor assumes little endian byte order.</p>                                                                                            |
| <i>&lt;Relational-Operator&gt;</i> | <p>Relational operator to express the relation between the packet data and the value:</p> <ul style="list-style-type: none"> <li>▪ &lt; - less than</li> <li>▪ &gt; - greater than</li> <li>▪ &lt;= - less than or equal to</li> <li>▪ &gt;= - greater than</li> <li>▪ = or is - equal to</li> <li>▪ != or is not - not equal to</li> </ul> |
| <i>&lt;Value&gt;</i>               | <p>One of the data types known to INSPECT (for example, an IP address, or an integer).</p>                                                                                                                                                                                                                                                  |

#### Explanations:

- The IP-based protocols are stored in the IP packet as a byte at offset 9.
  - To filter based on a Protocol encapsulated into IP, use this syntax:

```
[Expert@HostName]# fw monitor -e "accept [9:1]=<IANA_
Protocol_Number>;"
```

- The Layer 3 IP Addresses are stored in the IP packet as double words at offset 12 (Source address) and at offset 16 (Destination address).

- To filter based on a Source IP address, use this syntax:

```
[Expert@HostName]# fw monitor -e "accept [12:4,b]=<IP_
Address_in_Doted_Decimal_format>;"
```

- To filter based on a Destination IP address, use this syntax:

```
[Expert@HostName]# fw monitor -e "accept [16:4,b]=<IP_
Address_in_Doted_Decimal_format>;"
```

- The Layer 4 Ports are stored in the IP packet as a word at offset 20 (Source port) and at offset 22 (Destination port).

- To filter based on a Source port, use this syntax:

```
[Expert@HostName]# fw monitor -e "accept
[20:2,b]=<Port_Number_in_Decimal_format>;"
```

- To filter based on a Destination port, use this syntax:

```
[Expert@HostName]# fw monitor -e "accept
[22:2,b]=<Port_Number_in_Decimal_format>;"
```

#### Example filters:

- Capture everything between host X and host Y:

```
[Expert@HostName]# fw monitor -e "accept (([12:4,b]=x.x.x.x
, [16:4,b]=y.y.y.y) or ([12:4,b]=y.y.y.y ,
[16:4,b]=x.x.x.x));"
```

- Capture everything on port X:

```
[Expert@HostName]# fw monitor -e "accept [20:2,b]=x or
[22:2,b]=x;" -o /var/log/fw_mon.cap
```

#### Example 7 - Capture traffic to/from specific network

You must specify the *network address* and *length of network mask* (number of bits).

There are 3 options:

| Traffic direction    | Expression                                           |
|----------------------|------------------------------------------------------|
| To or From a network | "net (<Network_IP_Address>, <Mask_Length>), accept;" |

| Traffic direction | Expression                                                                        |
|-------------------|-----------------------------------------------------------------------------------|
| To a network      | <code>"to_net(&lt;Network_IP_Address&gt;, &lt;Mask_Length&gt;), accept;"</code>   |
| From a network    | <code>"from_net(&lt;Network_IP_Address&gt;, &lt;Mask_Length&gt;), accept;"</code> |

Example filters:

- Capture everything to/from network 192.168.33.0 / 24:

```
[Expert@HostName]# fw monitor -e "net(192.168.33.0, 24), accept;"
```

- Capture everything sent to network 192.168.33.0 / 24:

```
[Expert@HostName]# fw monitor -e "to_net(192.168.33.0, 24), accept;"
```

- Capture everything sent from network 192.168.33.0 / 24:

```
[Expert@HostName]# fw monitor -e "from_net(192.168.33.0, 24), accept;"
```

### Example 8 - Filter out irrelevant "noise"

Filter in only TCP protocol, and HTTP and HTTPS ports

Filter out the SSH and FW Logs

```
[Expert@HostName]# fw monitor -e "accept (ip_p=6) and (not (sport=22 or dport=22)) and (not (sport=257 or dport=257)) and ((dport=80 or dport=443) or (sport=80 or sport=443));" -o /var/log/fw_mon.cap
```

### Examples for the "-F" parameter

You can specify up to 5 capture filters with this parameter (up to 5 instances of the "-F" parameter in the syntax).

The FW Monitor performs the logical "OR" between all specified simple capture filters.

Value 0 is used as "any".

**Example 1 - Capture everything**

```
[Expert@HostName]# fw monitor -F "0,0,0,0,0" -o /var/log/fw_mon.cap
```

**Example 2 - Capture traffic to / from specific hosts**

- Capture all traffic from Source IP x.x.x.x (any port) to Destination IP y.y.y.y (any port), over all protocols:

```
[Expert@HostName]# fw monitor -F "x.x.x.x,0,y.y.y.y,0,0" -o /var/log/fw_mon.cap
```

- Capture all traffic between Host x.x.x.x (any port) and Host y.y.y.y (any port), over all protocols:

```
[Expert@HostName]# fw monitor -F "x.x.x.x,0,y.y.y.y,0,0" -F "y.y.y.y,0, x.x.x.x ,0,0" -o /var/log/fw_mon.cap
```

**Example 3 - Capture traffic to / from specific ports**

- Capture traffic from any Source IP from Source Port X to any Destination IP to Destination Port Y, over all protocols:

```
[Expert@HostName]# fw monitor -F "0,x,0,y,0" -o /var/log/fw_mon.cap
```

- Capture traffic between all hosts, between Port X and Port Y, over all protocols:

```
[Expert@HostName]# fw monitor -F "0,x,0,y,0" -F "0,y,0,x,0" -o /var/log/fw_mon.cap
```

**Example 4 - Capture traffic over specific protocol**

- Capture traffic between all hosts, between all ports, over a Protocol with assigned number X:

```
[Expert@HostName]# fw monitor -F "0,0,0,0,x" -o /var/log/fw_mon.cap
```

**Example 5 - Capture traffic between specific hosts between specific ports over specific protocol**

```
[Expert@HostName]# fw monitor -F "a.a.a.a,b,c.c.c.c,d,e" -F "c.c.c.c,d,a.a.a.a,b,e" -o /var/log/fw_mon.cap
```

To capture only HTTP traffic between the Client 1.1.1.1 and the Server 2.2.2.2:

```
fw montior -F "1.1.1.1,0,2.2.2.2,80,6" -F  
"2.2.2.2,80,1.1.1.1,0,6" -o /var/log/fw_mon.cap
```

# fw repairlog

## Description

Check Point Security log file (\$FWDIR/log/\*.log) and Audit log files (\$FWDIR/log/\*.adtlog) are databases, with special pointer files.

If these log pointer files become corrupted (which causes the inability to read the log file), this command can rebuild them.

| Log File Type | Log File Location    | Log Pointer Files                                                            |
|---------------|----------------------|------------------------------------------------------------------------------|
| Security log  | \$FWDIR/log/*.log    | *.logptr<br>*.logaccount_ptr<br>*.loginitial_ptr<br>*.logLuuidDB             |
| Audit log     | \$FWDIR/log/*.adtlog | *.adtlogptr<br>*.adtlogaccount_ptr<br>*.adtloginitial_ptr<br>*.adtlogLuuidDB |

 **Important** - You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).

## Syntax

```
fw [-d] repairlog [-u] <Name of Log File>
```

## Parameters

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d                 | Runs the command in debug mode.<br>Use only if you troubleshoot the command itself.<br> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session. |
| -u                 | Specifies to rebuild the unification chains in the log file.                                                                                                                                                                                                                                                                               |
| <Name of Log File> | The name of the log file to repair.                                                                                                                                                                                                                                                                                                        |

## Example - Repairing the Audit log file

```
fw repairlog -u 2019-06-17_000000.adtlog
```

# fw sam

## Description

Manages the Suspicious Activity Monitoring (SAM) rules. You can use the SAM rules to block connections to and from IP addresses without the need to change or reinstall the Security Policy. For more information, see [sk112061](#).

You can create the Suspicious Activity Rules in two ways:

- In SmartConsole from Monitoring Results
- In CLI with the `fw sam` command

## Notes:

- See the "`fw sam_policy`" and "`sam_alert`" commands.
- SAM rules consume some CPU resources on Security Gateway.
  - ★ **Best Practice** - The SAM Policy rules consume some CPU resources on Security Gateway. Set an expiration for rules that gives you time to investigate, but does not affect performance. Keep only the required SAM Policy rules. If you confirm that an activity is risky, edit the Security Policy, educate users, or otherwise handle the risk.
- Logs for enforced SAM rules (configured with the `fw sam` command) are stored in the `$FWDIR/log/sam.dat` file.  
By design, the file is purged when the number of stored entries reaches 100,000.  
This data log file contains the records in one of these formats:
 

|                                                                                                             |
|-------------------------------------------------------------------------------------------------------------|
| <code>&lt;type&gt;,&lt;actions&gt;,&lt;expire&gt;,&lt;ipaddr&gt;</code>                                     |
| <code>&lt;type&gt;,&lt;actions&gt;,&lt;expire&gt;,&lt;src&gt;,&lt;dst&gt;,&lt;dport&gt;,&lt;ip_p&gt;</code> |
- SAM Requests are stored on the Security Gateway in the kernel table `sam_requests`.
- IP Addresses that are blocked by SAM rules, are stored on the Security Gateway in the kernel table `sam_blocked_ips`.

## Note - To configure SAM Server settings for a Security Gateway or Cluster:

1. Connect with SmartConsole to the applicable Security Management Server or Domain Management Server.
2. From the left navigation panel, click **Gateways & Servers**.
3. Open the Security Gateway or Cluster object.
4. From the left tree, click **Other > SAM**.
5. Configure the settings.
6. Click **OK**.
7. Install the Access Control Policy on this Security Gateway or Cluster object.

## Important:

- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.
- VSNext mode and Traditional VSX mode do **not** support Suspicious Activity Monitoring (SAM) Rules. See [sk79700](#).

## Syntax

- To add or cancel a SAM rule according to criteria:

```
fw [-d] sam [-v] [-s <SAM Server>] [-S <SIC Name of SAM
Server>] [-f <Security Gateway>] [-t <Timeout>] [-l <Log
Type>] [-C] [-e <key=val>]+ [-r] -{n|i|I|j|J} <Criteria>
```

- To delete all SAM rules:

```
fw [-d] sam [-v] [-s <SAM Server>] [-S <SIC Name of SAM
Server>] [-f <Security Gateway>] -D
```

- To monitor all SAM rules:

```
fw [-d] sam [-v] [-s <SAM Server>] [-S <SIC Name of SAM
Server>] [-f <Security Gateway>] [-r] -M -{i|j|n|b|q} all
```

- To monitor SAM rules according to criteria:

```
fw [-d] sam [-v] [-s <SAM Server>] [-S <SIC Name of SAM
Server>] [-f <Security Gateway>] [-r] -M -{i|j|n|b|q}
<Criteria>
```

## Parameters

| Parameter | Description                                                                                                                                                                                                                                                                                                                                |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d        | Runs the command in debug mode.<br>Use only if you troubleshoot the command itself.<br> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session. |
| -v        | Enables verbose mode.<br>In this mode, the command writes one message to <i>stderr</i> for each Security Gateway, on which the command is enforced. These messages show whether the command was successful or not.                                                                                                                         |

| Parameter                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-s &lt;SAM Server&gt;</code>             | <p>Specifies the IP address (in the X.X.X.X format) or resolvable HostName of the Security Gateway that enforces the command.</p> <p>The default is <code>localhost</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>-S &lt;SIC Name of SAM Server&gt;</code> | <p>Specifies the SIC name for the SAM server to be contacted. It is expected that the SAM server has this SIC name, otherwise the connection fails.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>■ If you do not explicitly specify the SIC name, the connection continues without the SIC names comparison.</li> <li>■ For more information about enabling the SIC, refer to the OPSEC API Specification.</li> <li>■ On VSX Gateway, run the <code>fw vsx showncs -vs &lt;VSID&gt;</code> command to show the SIC name for the applicable Virtual System.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

Specifies to enforce the action on all managed Security Gateways, where SAM Server runs.<br/>You can use this syntax only on Security Management Server or Domain Management Server.</li> <li>■ <b>localhost</b> - Specifies to enforce the action on this local Check Point server (on which the <code>fw sam</code> command is executed).<br/>You can use this syntax only on Security Gateway or StandAlone.</li> <li>■ <b>Gateways</b> - Specifies to enforce the action on all objects defined as Security Gateways, on which SAM Server runs.<br/>You can use this syntax only on Security Management Server or Domain Management Server.</li> <li>■ <b>Name of Security Gateway object</b> - Specifies to enforce the action on this specific Security Gateway object.<br/>You can use this syntax only on Security Management Server or Domain Management Server.</li> <li>■ <b>Name of Group object</b> - Specifies to enforce the action on all specific Security Gateways in this Group object.</li> </ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>■ You can use this syntax only on Security Management Server or Domain Management Server.</li> <li>■ VSX Gateways and VSX Cluster Members do not support Suspicious Activity Monitoring (SAM) Rules. See <a href="#">sk79700</a>.</li> </ul> |

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -D               | <p>Cancels all inhibit ("-i", "-j", "-I", "-J") and notify ("-n") parameters.</p> <p> <b>Notes:</b></p> <ul style="list-style-type: none"> <li>■ To "uninhibit" the inhibited connections, run the <code>fw sam</code> command with the "-C" or "-D" parameters.</li> <li>■ It is also possible to use this command for active SAM requests.</li> </ul>                                                                      |
| -C               | <p>Cancels the <code>fw sam</code> command to inhibit connections with the specified parameters.</p> <p> <b>Notes:</b></p> <ul style="list-style-type: none"> <li>■ These connections are no longer inhibited (no longer rejected or dropped).</li> <li>■ The command parameters must match the parameters in the original <code>fw sam</code> command, except for the <code>-t &lt;Timeout&gt;</code> parameter.</li> </ul> |
| -t<br><Timeout>  | <p>Specifies the time period (in seconds), during which the action is enforced. The default is forever, or until you cancel the <code>fw sam</code> command.</p>                                                                                                                                                                                                                                                                                                                                              |
| -l <Log<br>Type> | <p>Specifies the type of the log for enforced action:</p> <ul style="list-style-type: none"> <li>■ <code>nolog</code> - Does not generate Log / Alert at all</li> <li>■ <code>short_noalert</code> - Generates a Log</li> <li>■ <code>short_alert</code> - Generates an Alert</li> <li>■ <code>long_noalert</code> - Generates a Log</li> <li>■ <code>long_alert</code> - Generates an Alert (this is the default)</li> </ul>                                                                                 |
| -e<br><key=val>+ | <p>Specifies rule information based on the keys and the provided values. Multiple keys are separated by the plus sign (+). Available keys are (each is limited to 100 characters):</p> <ul style="list-style-type: none"> <li>■ <code>name</code> - Security rule name</li> <li>■ <code>comment</code> - Security rule comment</li> <li>■ <code>originator</code> - Security rule originator's username</li> </ul>                                                                                            |
| -r               | <p>Specifies not to resolve IP addresses.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| -n               | <p>Specifies to generate a "Notify" long-format log entry.</p> <p> <b>Notes:</b></p> <ul style="list-style-type: none"> <li>■ This parameter generates an alert when connections that match the specified services or IP addresses pass through the Security Gateway.</li> <li>■ This action does not inhibit / close connections.</li> </ul>                                                                              |

| Parameter  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -i         | <p>Inhibits (drops or rejects) new connections with the specified parameters.</p> <p> <b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ Each inhibited connection is logged according to the log type.</li> <li>▪ Matching connections are rejected.</li> </ul>                                                                                                     |
| -I         | <p>Inhibits (drops or rejects) new connections with the specified parameters, and closes all existing connections with the specified parameters.</p> <p> <b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ Matching connections are rejected.</li> <li>▪ Each inhibited connection is logged according to the log type.</li> </ul>                                  |
| -j         | <p>Inhibits (drops or rejects) new connections with the specified parameters.</p> <p> <b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ Matching connections are dropped.</li> <li>▪ Each inhibited connection is logged according to the log type.</li> </ul>                                                                                                      |
| -J         | <p>Inhibits new connections with the specified parameters, and closes all existing connections with the specified parameters.</p> <p> <b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ Matching connections are dropped.</li> <li>▪ Each inhibited connection is logged according to the log type.</li> </ul>                                                    |
| -b         | Bypasses new connections with the specified parameters.                                                                                                                                                                                                                                                                                                                                                                                                       |
| -q         | Quarantines new connections with the specified parameters.                                                                                                                                                                                                                                                                                                                                                                                                    |
| -M         | Monitors the active SAM requests with the specified actions and criteria.                                                                                                                                                                                                                                                                                                                                                                                     |
| all        | Gets all active SAM requests. This is used for monitoring purposes only.                                                                                                                                                                                                                                                                                                                                                                                      |
| <Criteria> | <p>Criteria are used to match connections.</p> <p>The criteria are composed of various combinations of the following parameters:</p> <ul style="list-style-type: none"> <li>▪ Source IP Address</li> <li>▪ Source Netmask</li> <li>▪ Destination IP Address</li> <li>▪ Destination Netmask</li> <li>▪ Port (see <a href="#">IANA Service Name and Port Number Registry</a>)</li> <li>▪ Protocol Number (see <a href="#">IANA Protocol Numbers</a>)</li> </ul> |

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           | <p>Possible combinations are (see the explanations below this table):</p> <ul style="list-style-type: none"> <li>■ <code>src &lt;IP&gt;</code></li> <li>■ <code>dst &lt;IP&gt;</code></li> <li>■ <code>any &lt;IP&gt;</code></li> <li>■ <code>subsrc &lt;IP&gt; &lt;Netmask&gt;</code></li> <li>■ <code>subdst &lt;IP&gt; &lt;Netmask&gt;</code></li> <li>■ <code>subany &lt;IP&gt; &lt;Netmask&gt;</code></li> <li>■ <code>srv &lt;Src IP&gt; &lt;Dest IP&gt; &lt;Port&gt; &lt;Protocol&gt;</code></li> <li>■ <code>subsrv &lt;Src IP&gt; &lt;Src Netmask&gt; &lt;Dest IP&gt; &lt;Dest Netmask&gt; &lt;Port&gt; &lt;Protocol&gt;</code></li> <li>■ <code>subsrvs &lt;Src IP&gt; &lt;Src Netmask&gt; &lt;Dest IP&gt; &lt;Port&gt; &lt;Protocol&gt;</code></li> <li>■ <code>subsrvd &lt;Src IP&gt; &lt;Dest IP&gt; &lt;Dest Netmask&gt; &lt;Port&gt; &lt;Protocol&gt;</code></li> <li>■ <code>dstsrv &lt;Dest IP&gt; &lt;Port&gt; &lt;Protocol&gt;</code></li> <li>■ <code>subdstsrv &lt;Dest IP&gt; &lt;Dest Netmask&gt; &lt;Port&gt; &lt;Protocol&gt;</code></li> <li>■ <code>srcpr &lt;IP&gt; &lt;Protocol&gt;</code></li> <li>■ <code>dstpr &lt;IP&gt; &lt;Protocol&gt;</code></li> <li>■ <code>subsrcpr &lt;IP&gt; &lt;Netmask&gt; &lt;Protocol&gt;</code></li> <li>■ <code>subdstpr &lt;IP&gt; &lt;Netmask&gt; &lt;Protocol&gt;</code></li> <li>■ <code>generic &lt;key=val&gt;</code></li> </ul> |

### Explanation for the <Criteria> syntax

| Parameter                                      | Description                                                                           |
|------------------------------------------------|---------------------------------------------------------------------------------------|
| <code>src &lt;IP&gt;</code>                    | Matches the Source IP address of the connection.                                      |
| <code>dst &lt;IP&gt;</code>                    | Matches the Destination IP address of the connection.                                 |
| <code>any &lt;IP&gt;</code>                    | Matches either the Source IP address or the Destination IP address of the connection. |
| <code>subsrc &lt;IP&gt; &lt;Netmask&gt;</code> | Matches the Source IP address of the connections according to the netmask.            |
| <code>subdst &lt;IP&gt; &lt;Netmask&gt;</code> | Matches the Destination IP address of the connections according to the netmask.       |

| Parameter                                                                                                                | Description                                                                                                                                                                       |

# fw sam\_policy

## Description

Manages the Suspicious Activity Policy editor that works with these types of rules:

- Suspicious Activity Monitoring (SAM) rules.

See [sk112061: How to create and view Suspicious Activity Monitoring \(SAM\) Rules](#).

- Rate Limiting rules.

See [sk182350 - How to configure Rate Limiting rules for DoS Mitigation](#).

Also, see these commands:

- ["fw sam" on page 295](#)
- ["sam\\_alert" on page 404](#)

### Notes:

- These commands are interchangeable:
  - For IPv4: "fw sam\_policy" and "fw samp".
  - For IPv6: "fw6 sam\_policy" and "fw6 samp".
- You can run these commands in Gaia Clish, or Expert mode.
- Security Gateway stores the SAM Policy rules in the `$FWDIR/database/sam_policy.db` file.
- Security Gateway stores the SAM Policy management settings in the `$FWDIR/database/sam_policy.mng` file.

### Important:

- Configuration you make with these commands, survives reboot.
- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.
- VSNext mode and Traditional VSX mode do **not** support Suspicious Activity Monitoring (SAM) Rules. See [sk79700](#).

**Best Practice** - The SAM Policy rules consume some CPU resources on Security Gateway. Set an expiration for rules that gives you time to investigate, but does not affect performance. Keep only the required SAM Policy rules. If you confirm that an activity is risky, edit the Security Policy, educate users, or otherwise handle the risk.

## Syntax for IPv4

```
fw [-d] sam_policy  
    add <options>  
    batch  
    del <options>  
    get <options>
```

```
fw [-d] samp  
    add <options>  
    batch  
    del <options>  
    get <options>
```

## Syntax for IPv6

```
fw6 [-d] sam_policy  
    add <options>  
    batch  
    del <options>  
    get <options>
```

```
fw6 [-d] samp  
    add <options>  
    batch  
    del <options>  
    get <options>
```

## Parameters

| Parameter     | Description                                                                                                                                                                                                                                                          |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d            | <p>Runs the command in debug mode.<br/>Use only if you troubleshoot the command itself.</p> <p>★ <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p> |
| add <options> | <p>Adds one Rate Limiting rule one at a time.<br/>See "<a href="#">fw sam_policy add</a>" on page 306.</p>                                                                                                                                                           |
| batch         | <p>Adds or deletes many Rate Limiting rules at a time.<br/>See "<a href="#">fw sam_policy batch</a>" on page 319.</p>                                                                                                                                                |
| del <options> | <p>Deletes one configured Rate Limiting rule one at a time.<br/>See "<a href="#">fw sam_policy del</a>" on page 321.</p>                                                                                                                                             |
| get <options> | <p>Shows all the configured Rate Limiting rules.<br/>See "<a href="#">fw sam_policy get</a>" on page 324.</p>                                                                                                                                                        |

## fw sam\_policy add

### Description

The "fw sam\_policy add" and "fw6 sam\_policy add" commands:

- Add one Suspicious Activity Monitoring (SAM) rule at a time.
- Add one Rate Limiting rule at a time.

### Notes:

- These commands are interchangeable:
  - For IPv4: "fw sam\_policy" and "fw samp".
  - For IPv6: "fw6 sam\_policy" and "fw6 samp".
- You can run these commands in Gaia Clish, or Expert mode.
- Security Gateway stores the SAM Policy rules in the `$FWDIR/database/sam_policy.db` file.
- Security Gateway stores the SAM Policy management settings in the `$FWDIR/database/sam_policy.mng` file.

### Important:

- Configuration you make with these commands, survives reboot.
- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.
- VSNext mode and Traditional VSX mode do **not** support Suspicious Activity Monitoring (SAM) Rules. See [sk79700](#).

- ★ **Best Practice** - The SAM Policy rules consume some CPU resources on Security Gateway. Set an expiration for rules that gives you time to investigate, but does not affect performance. Keep only the required SAM Policy rules. If you confirm that an activity is risky, edit the Security Policy, educate users, or otherwise handle the risk.

### Syntax to configure a Suspicious Activity Monitoring (SAM) rule for IPv4

```
fw [-d] sam_policy add [-u] -a {d|n|b} [-l {r|a}] [-t <Timeout>]
[-f <Target>] [-n <"Rule Name">] [-c <"Rule Comment">] [-o <"Rule
Originator">] [-z "<Zone>"] ip <IP Filter Arguments>
```

### Syntax to configure a Suspicious Activity Monitoring (SAM) rule for IPv6

```
fw6 [-d] sam_policy add [-u] -a {d|n|b} [-l {r|a}] [-t <Timeout>]
[-f <Target>] [-n <"Rule Name">] [-c <"Rule Comment">] [-o <"Rule
Originator">] [-z "<Zone>"] ip <IP Filter Arguments>
```

## Syntax to configure a Rate Limiting rule for IPv4

```
fw [-d] sam_policy add [-u] -a {d|n|b} [-l {r|a}] [-t <Timeout>]
[-f <Target>] [-n <"Rule Name">] [-c <"Rule Comment">] [-o <"Rule
Originator">] [-z "<Zone>"] quota <Quota Filter Arguments>
```

## Syntax to configure a Rate Limiting rule for IPv6

```
fw6 [-d] sam_policy add [-u] -a {d|n|b} [-l {r|a}] [-t <Timeout>]
[-f <Target>] [-n <"Rule Name">] [-c <"Rule Comment">] [-o <"Rule
Originator">] [-z "<Zone>"] quota <Quota Filter Arguments>
```

## Parameters

| Parameter      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d             | Runs the command in debug mode.<br>Use only if you troubleshoot the command itself.<br> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.                                                                                                                                                                                                                                                |
| -u             | Optional.<br>Specifies that the rule category is User-defined.<br>Default rule category is Auto.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| -a {d   n   b} | Mandatory.<br>Specifies the rule action if the traffic matches the rule conditions: <ul style="list-style-type: none"> <li>■ d - Drop the connection.</li> <li>■ n - Notify (generate a log) about the connection and let it through.</li> <li>■ b - Bypass the connection - let it through without checking it against the policy rules.</li> </ul> <b>Note</b> - Rules with action set to <i>Bypass</i> cannot have a log or limit specification. Bypassed packets and connections do not count towards overall number of packets and connection for limit enforcement of type ratio. |
| -l {r   a}     | Optional.<br>Specifies which type of log to generate for this rule for all traffic that matches: <ul style="list-style-type: none"> <li>■ -r - Generate a regular log</li> <li>■ -a - Generate an alert log</li> </ul>                                                                                                                                                                                                                                                                                                                                                                  |

| Parameter                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|---------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>quota</code><br><code>&lt;Quota</code><br><code>Filter</code><br><code>Arguments&gt;</code> | <p>Mandatory (use this <code>quota</code> parameter, or the <code>ip</code> parameter).<br/> Configures the <i>Rate Limiting</i> rule.<br/> Specifies the Quota Filter Arguments for the Rate Limiting rule (see the explanations below):</p> <ul style="list-style-type: none"> <li>■ <code>[flush true]</code></li> <li>■ <code>[source-negated {true   false}] source &lt;Source&gt;</code></li> <li>■ <code>[destination-negated {true   false}] destination &lt;Destination&gt;</code></li> <li>■ <code>[service-negated {true   false}] service &lt;Protocol and Port numbers&gt;</code></li> <li>■ <code>[&lt;Limit1 Name&gt; &lt;Limit1 Value&gt;] [&lt;Limit2 Name&gt; &lt;Limit2 Value&gt;] ... [&lt;LimitN Name&gt; &lt;LimitN Value&gt;]</code></li> <li>■ <code>[track &lt;Track&gt;]</code></li> </ul> <p> <b>Important:</b></p> <ul style="list-style-type: none"> <li>■ The Quota rules are not applied immediately to the Security Gateway. They are only registered in the Suspicious Activity Monitoring (SAM) policy database. To apply all the rules from the SAM policy database immediately, add "flush true" in the <code>fw sam_policy add</code> command syntax.</li> <li>■ Explanation:<br/> For new connections rate (and for any rate limiting in general), when a rule's limit is violated, the Security Gateway also drops all packets that match the rule.<br/> The Security Gateway computes new connection rates on a per-second basis.<br/> At the start of the 1-second timer, the Security Gateway allows all packets, including packets for existing connections.<br/> If, at some point, during that 1 second period, there are too many new connections, then the Security Gateway blocks all remaining packets for the remainder of that 1-second interval.<br/> At the start of the next 1-second interval, the counters are reset, and the process starts over - the Security Gateway allows packets to pass again up to the point, where the rule's limit is violated.</li> </ul> |

## Explanation for the *IP Filter Arguments* syntax for Suspicious Activity Monitoring (SAM) rules

| Argument              | Description                                                                                  |
|-----------------------|----------------------------------------------------------------------------------------------|
| -C                    | Specifies that open connections should be closed.                                            |
| -s <Source IP>        | Specifies the Source IP address.                                                             |
| -m <Source Mask>      | Specifies the Source subnet mask (in dotted decimal format - x.y.z.w).                       |
| -d <Destination IP>   | Specifies the Destination IP address.                                                        |
| -M <Destination Mask> | Specifies the Destination subnet mask (in dotted decimal format - x.y.z.w).                  |
| -p <Port>             | Specifies the port number (see <a href="#">IANA Service Name and Port Number Registry</a> ). |
| -r <Protocol>         | Specifies the protocol number (see <a href="#">IANA Protocol Numbers</a> ).                  |

Explanation for the *Quota Filter Arguments* syntax for Rate Limiting rules

| Argument                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Argument        | Description                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [track <Track>] | <p>Specifies the tracking option:</p> <ul style="list-style-type: none"> <li>■ <code>source</code><br/>Counts connections, packets, and bytes for specific source IP address, and not cumulatively for this rule.</li> <li>■ <code>source-service</code><br/>Counts connections, packets, and bytes for specific source IP address, and for specific IP protocol and destination port, and not cumulatively for this rule.</li> </ul> |

## Examples

### Example 1 - Rate Limiting rule with a range

```
fw sam_policy add -a d -l r -t 3600 quota service any source range:172.16.7.11-172.16.7.13 new-conn-rate 5 flush true
```

#### Explanations:

- This rule drops packets for all connections (`-a d`) that exceed the quota set by this rule, including packets for existing connections.
- This rule logs packets (`-l r`) that exceed the quota set by this rule.
- This rule will expire in 3600 seconds (`-t 3600`).
- This rule limits the rate of creation of new connections to 5 connections per second (`new-conn-rate 5`) for any traffic (`service any`) from the source IP addresses in the range 172.16.7.11 - 172.16.7.13 (`source range:172.16.7.11-172.16.7.13`).

**Note** - The limit of the total number of log entries per second is configured with the *fwaccel dos config set -n <rate>* command.

- This rule will be compiled and loaded on the SecureXL, together with other rules in the Suspicious Activity Monitoring (SAM) policy database immediately, because this rule includes the "flush true" parameter.

## Example 2 - Rate Limiting rule with a service specification

```
fw sam_policy add -a n -l r quota service 1,50-51,6/443,17/53 service-negated true source cc:QQ byte-rate 0
```

### Explanations:

- This rule logs and lets through all packets (`-a n`) that exceed the quota set by this rule.
- This rule does not expire (the `timeout` parameter is not specified). To cancel it, you must delete it explicitly.
- This rule applies to all packets except (`service-negated true`) the packets with IP protocol number 1, 50-51, 6 port 443 and 17 port 53 (`service 1,50-51,6/443,17/53`).
- This rule applies to all packets from source IP addresses that are assigned to the country with specified country code (`cc:QQ`).
- This rule does not let any traffic through (`byte-rate 0`) except the packets with IP protocol number 1, 50-51, 6 port 443 and 17 port 53.
- This rule will not be compiled and installed on the SecureXL immediately, because it does not include the "`flush true`" parameter.

## Example 3 - Rate Limiting rule with ASN

```
fw sam_policy -a d quota source asn:AS64500,cidr:[::FFFF:C0A8:1100]/120 service any pkt-rate 0
```

### Explanations:

- This rule drops (`-a d`) all packets that match this rule.
- This rule does not expire (the `timeout` parameter is not specified). To cancel it, you must delete it explicitly.
- This rule applies to packets from the Autonomous System number 64500 (`asn:AS64500`).
- This rule applies to packets from source IPv6 addresses FFFF:C0A8:1100/120 (`cidr:[::FFFF:C0A8:1100]/120`).
- This rule applies to all traffic (`service any`).
- This rule does not let any traffic through (`pkt-rate 0`).
- This rule will not be compiled and installed on the SecureXL immediately, because it does not include the "`flush true`" parameter.

## Example 4 - Rate Limiting rule with an Allow List

```
fw sam_policy add -a b quota source range:172.16.8.17-172.16.9.121 service 6/80
```

### Explanations:

- This rule bypasses (`-a b`) all packets that match this rule.

**Note** - The Access Control Policy and other types of security policy rules still apply.

- This rule does not expire (the `timeout` parameter is not specified). To cancel it, you must delete it explicitly.
- This rule applies to packets from the source IP addresses in the range 172.16.8.17 - 172.16.9.121 (`range:172.16.8.17-172.16.9.121`).
- This rule applies to packets sent to TCP port 80 (`service 6/80`).
- This rule will not be compiled and installed on the SecureXL immediately, because it does not include the "`flush true`" parameter.

### Example 5 - Rate Limiting rule with tracking

```
fw sam_policy add -a d quota service any source-negated true source cc:QQ concurrent-conns-ratio 655 track source
```

#### Explanations:

- This rule drops (`-a d`) all packets that match this rule.
- This rule does not log any packets (the `-l r` parameter is not specified).
- This rule does not expire (the `timeout` parameter is not specified). To cancel it, you must delete it explicitly.
- This rule applies to all traffic (`service any`).
- This rule applies to all sources except (`source-negated true`) the source IP addresses that are assigned to the country with specified country code (`cc:QQ`).
- This rule limits the maximum number of concurrent active connections to  $655/65536 \approx 1\%$  (`concurrent-conns-ratio 655`) for any traffic (`service any`) except (`source-negated true`) the connections from the source IP addresses that are assigned to the country with specified country code (`cc:QQ`).
- This rule counts connections, packets, and bytes for traffic only from sources that match this rule, and not cumulatively for this rule.
- This rule will not be compiled and installed on the SecureXL immediately, because it does not include the "`flush true`" parameter.

## fw sam\_policy batch

### Description

The "fw sam\_policy batch" and "fw6 sam\_policy batch" commands:

- Add and delete many Suspicious Activity Monitoring (SAM) rules at a time.
- Add and delete many Rate Limiting rules at a time.

#### Notes:

- These commands are interchangeable:
  - For IPv4: "fw sam\_policy" and "fw samp".
  - For IPv6: "fw6 sam\_policy" and "fw6 samp".
- You can run these commands in Gaia Clish, or Expert mode.
- Security Gateway stores the SAM Policy rules in the `$FWDIR/database/sam_policy.db` file.
- Security Gateway stores the SAM Policy management settings in the `$FWDIR/database/sam_policy.mng` file.

#### Important:

- Configuration you make with these commands, survives reboot.
- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.
- VSNext mode and Traditional VSX mode do **not** support Suspicious Activity Monitoring (SAM) Rules. See [sk79700](#).

**Best Practice** - The SAM Policy rules consume some CPU resources on Security Gateway. Set an expiration for rules that gives you time to investigate, but does not affect performance. Keep only the required SAM Policy rules. If you confirm that an activity is risky, edit the Security Policy, educate users, or otherwise handle the risk.

### Procedure

#### 1. Start the batch mode

- For IPv4, run:

```
fw sam_policy batch << EOF
```

- For IPv6, run:

```
fw6 sam_policy batch << EOF
```

## 2. Enter the applicable commands

- Enter one "add" or "del" command on each line, on as many lines as necessary.

Start each line with only "add" or "del" parameter (not with "fw samp").

- Use the same set of parameters and values as described in these commands:
  - fw sam\_policy add
  - fw sam\_policy del
- Terminate each line with a Return (ASCII 10 - Line Feed) character (press Enter).

## 3. End the batch mode

Type EOF and press Enter.

### Example of a Rate Limiting rule for IPv4

```
[Expert@HostName]# fw samp batch <<EOF
add -a d -l r -t 3600 -c "Limit\ conn\ rate\ to\ 5\ conn/sec from\ these\ sources" quota service
any source range:172.16.7.13-172.16.7.13 new-conn-rate 5

del <501f6ef0,00000000,cb38a8c0,0a0afffe>

add -a b quota source range:172.16.8.17-172.16.9.121 service 6/80

EOF
[Expert@HostName]#
```

## fw sam\_policy del

### Description

The "fw sam\_policy del" and "fw6 sam\_policy del" commands:

- Delete one configured Suspicious Activity Monitoring (SAM) rule at a time.
- Delete one configured Rate Limiting rule at a time.

#### Notes:

- These commands are interchangeable:
  - For IPv4: "fw sam\_policy" and "fw samp".
  - For IPv6: "fw6 sam\_policy" and "fw6 samp".
- You can run these commands in Gaia Clish, or Expert mode.
- Security Gateway stores the SAM Policy rules in the `$FWDIR/database/sam_policy.db` file.
- Security Gateway stores the SAM Policy management settings in the `$FWDIR/database/sam_policy.mng` file.

#### Important:

- Configuration you make with these commands, survives reboot.
- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.
- VSNext mode and Traditional VSX mode do **not** support Suspicious Activity Monitoring (SAM) Rules. See [sk79700](#).

**Best Practice** - The SAM Policy rules consume some CPU resources on Security Gateway. Set an expiration for rules that gives you time to investigate, but does not affect performance. Keep only the required SAM Policy rules. If you confirm that an activity is risky, edit the Security Policy, educate users, or otherwise handle the risk.

### Syntax for IPv4

```
fw [-d] sam_policy del '<Rule UID>'
```

### Syntax for IPv6

```
fw6 [-d] sam_policy del '<Rule UID>'
```

## Parameters

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                         |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d           | Runs the command in debug mode.<br>Use only if you troubleshoot the command itself.<br> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.            |
| '<Rule UID>' | Specifies the UID of the rule you wish to delete.<br> <b>Important:</b> <ul style="list-style-type: none"> <li>▪ The quote marks and angle brackets ('&lt;...&gt;') are mandatory.</li> <li>▪ To see the Rule UID, run the "fw sam_policy get" command.</li> </ul> |

## Procedure

### 1. List all the existing rules in the Suspicious Activity Monitoring policy database

List all the existing rules in the Suspicious Activity Monitoring policy database.

- For IPv4, run:

```
fw sam_policy get
```

- For IPv6, run:

```
fw6 sam_policy get
```

The rules show in this format:

```
operation=add uid=<Value1,Value2,Value3,Value4> target=...
timeout=... action=... log= ... name= ... comment=...
originator= ... src_ip_addr=... req_tpe=...
```

Example for IPv4:

```
operation=add uid=<5ac3965f,00000000,3403a8c0,0000264a>
target=all timeout=300 action=notify log=log name=Test\ Rule
comment=Notify\ about\ traffic\ from\ 1.1.1.1
originator=John\ Doe src_ip_addr=1.1.1.1 req_tpe=ip
```

## 2. Delete a rule from the list by its UID

- For IPv4, run:

```
fw [-d] sam_policy del '<Rule UID>'
```

- For IPv6, run:

```
fw6 [-d] sam_policy del '<Rule UID>'
```

Example for IPv4:

```
fw samp del '<5ac3965f,00000000,3403a8c0,0000264a>'
```

## 3. Add the flush-only rule

- For IPv4, run:

```
fw samp add -t 2 quota flush true
```

- For IPv6, run:

```
fw6 samp add -t 2 quota flush true
```

Explanation:

The "fw samp del" and "fw6 samp del" commands only remove a rule from the persistent database. The Security Gateway continues to enforce the deleted rule until the next time you compiled and load a policy. To force the rule deletion immediately, you must enter a flush-only rule right after the "fw samp del" and "fw6 samp del" command. This flush-only rule immediately deletes the rule you specified in the previous step, and times out in 2 seconds.

- ★ **Best Practice** - Specify a short timeout period for the flush-only rules. This prevents accumulation of rules that are obsolete in the database.

## fw sam\_policy get

### Description

The "fw sam\_policy get" and "fw6 sam\_policy get" commands:

- Show all the configured Suspicious Activity Monitoring (SAM) rules.
- Show all the configured Rate Limiting rules.

### Notes:

- These commands are interchangeable:
  - For IPv4: "fw sam\_policy" and "fw samp".
  - For IPv6: "fw6 sam\_policy" and "fw6 samp".
- You can run these commands in Gaia Clish, or Expert mode.
- Security Gateway stores the SAM Policy rules in the `$FWDIR/database/sam_policy.db` file.
- Security Gateway stores the SAM Policy management settings in the `$FWDIR/database/sam_policy.mng` file.

### Important:

- Configuration you make with these commands, survives reboot.
- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.
- VSNext mode and Traditional VSX mode do **not** support Suspicious Activity Monitoring (SAM) Rules. See [sk79700](#).

- ★ **Best Practice** - The SAM Policy rules consume some CPU resources on Security Gateway. Set an expiration for rules that gives you time to investigate, but does not affect performance. Keep only the required SAM Policy rules. If you confirm that an activity is risky, edit the Security Policy, educate users, or otherwise handle the risk.

### Syntax for IPv4

```
fw [-d] sam_policy get [-l] [-u '<Rule UID>'] [-k '<Key>' -t
<Type> [{-v '<Value>'}] [-n]]
```

### Syntax for IPv6

```
fw6 [-d] sam_policy get [-l] [-u '<Rule UID>'] [-k '<Key>' -t
<Type> [{-v '<Value>'}] [-n]]
```

## Parameters

**Note** - All these parameters are optional.

| Parameter       | Description                                                                                                                                                                                                                                                                                                                        |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d              | Runs the command in debug mode.<br>Use only if you troubleshoot the command itself.<br>★ <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.                                                                           |
| -l              | Controls how to print the rules: <ul style="list-style-type: none"> <li>■ In the default format (without "-l"), the output shows each rule on a separate line.</li> <li>■ In the list format (with "-l"), the output shows each parameter of a rule on a separate line.</li> <li>■ See the "fw sam_policy add" command.</li> </ul> |
| -u '<Rule UID>' | Prints the rule specified by its Rule UID or its zero-based rule index.<br>The quote marks and angle brackets ('<...>') are mandatory.                                                                                                                                                                                             |
| -k '<Key>'      | Prints the rules with the specified predicate key.<br>The quote marks are mandatory.                                                                                                                                                                                                                                               |
| -t <Type>       | Prints the rules with the specified predicate type.<br>For Rate Limiting rules, you must always use "-t in".                                                                                                                                                                                                                       |
| +{-v '<Value>'} | Prints the rules with the specified predicate values.<br>The quote marks are mandatory.                                                                                                                                                                                                                                            |
| -n              | Negates the condition specified by these predicate parameters: <ul style="list-style-type: none"> <li>■ -k</li> <li>■ -t</li> <li>■ +-v</li> </ul>                                                                                                                                                                                 |

## Examples

### Example 1 - Output in the default format

```
[Expert@HostName:0]# fw samp get

operation=add uid=<5ac3965f,00000000,3403a8c0,0000264a> target=all timeout=300 action=notify
log=log name=Test\ Rule comment=Notify\ about\ traffic\ from\ 1.1.1.1 originator=John\ Doe
src_ip_addr=1.1.1.1 req_tpe=ip
```

**Example 2 - Output in the list format**

```
[Expert@HostName:0]# fw samp get -l
uid
<5ac3965f,00000000,3403a8c0,0000264a>
target
all
timeout
2147483647
action
notify
log
log
name
Test\ Rule
comment
Notify\ about\ traffic\ from\ 1.1.1.1
originator
John\ Doe
src_ip_addr
1.1.1.1
req_type
ip
```

**Example 3 - Printing a rule by its Rule UID**

```
[Expert@HostName:0]# fw samp get -u '<5ac3965f,00000000,3403a8c0,0000264a>'
0
operation=add uid=<5ac3965f,00000000,3403a8c0,0000264a> target=all timeout=300 action=notify
log=log name=Test\ Rule comment=Notify\ about\ traffic\ from\ 1.1.1.1 originator=John\ Doe
src_ip_addr=1.1.1.1 req_tpe=ip
```

#### Example 4 - Printing rules that match the specified filters

```

[Expert@HostName:0]# fw samp get
no corresponding SAM policy requests
[Expert@HostName:0]#

```

# fw sdwan

## Description

- Shows the current installed SD-WAN Policy on the Security Gateway.
- Fetches the SD-WAN Policy from a local directory on the Security Gateway.

For more information about SD-WAN, see [sk180605](#).

**Important** - You can run this command in the Expert mode or in Gaia Clish.

## Syntax

- To show the built-in help:

```
fw sdwan
```

- To show the current installed SD-WAN policy on the Security Gateway:

```
fw [-d] sdwan stat
```

Also see "[cpsdwan](#)" on page 1031 - it provides more information.

- To fetch the SD-WAN policy stored locally on the Security Gateway in the default directory `$FWDIR/state/`:

```
fw [-d] sdwan fetch local
```

- To fetch the SD-WAN policy stored locally on the Security Gateway in the specified directory:

```
fw [-d] sdwan fetchlocal -d <Full Path to Directory>
```

**Warning** - It is **not** supported to run these commands manually (they can only be executed by internal tasks on the Security Gateway):

- `fw sdwan uninstall`
- `fw sdwan unload`

## Parameters

| Parameter                                      | Description                                                                                                                                                                                                                                                          |
|------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>fw -d ...</code>                         | <p>Runs the command in debug mode.<br/>Use only if you troubleshoot the command itself.</p> <p>★ <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p> |
| <code>-d &lt;Full Path to Directory&gt;</code> | Specifies the local directory on the Security Gateway, from which to fetch the policy files.                                                                                                                                                                         |

## Example

```
[Expert@MyGW:0]# fw sdwan stat
POLICY                DATE
SD-WAN Policy         Thu Dec 15 15:34:03 2023
[Expert@MyGW:0]#
```

# fw showuptables

## Description

Shows the formatted contents of the Unified Policy kernel tables.

### Important:

- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- On Scalable Platforms, you must connect to the applicable Security Group.

## Syntax

```
fw [-d] showuptables
    [-h]
    [-i]
```

## Parameters

| Parameter | Description                                                                                                                                                                                                                                                                                                                                |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d        | Runs the command in debug mode.<br>Use only if you troubleshoot the command itself.<br> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session. |
| -h        | Shows the built-in usage.                                                                                                                                                                                                                                                                                                                  |
| -i        | Shows the implied rules layers.                                                                                                                                                                                                                                                                                                            |

# fw stat

## Description

Shows the following information about the policy on the Security Gateway:

- Name of the installed policy.
- Date of the last policy installation.
- Names of the interfaces protected by the installed policy, and in which direction the policy protects them.

### Important:

- This command is outdated and exists only for backward compatibility with very old versions.  
Use the "cpstat -f policy fw" command instead (see ["cpstat" on page 1033](#)).
- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- On Scalable Platforms, you must connect to the applicable Security Group.

## Syntax

```
fw [-d] stat [-l | -s] [<Name of Object>]
```

## Parameters

| Parameter     | Description                                                                                                                                                                                                                                                                                                                                |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d            | Runs the command in debug mode.<br>Use only if you troubleshoot the command itself.<br> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session. |
| No Parameters | Shows default output - all information is on one line.                                                                                                                                                                                                                                                                                     |

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -l               | <p>Shows long output.</p> <p>Shows each interface and its protected traffic direction is on a separate line.</p> <p>In addition, shows this information:</p> <ul style="list-style-type: none"> <li>■ <b>Total</b> - Number of packets the Security Gateway received on this interface</li> <li>■ <b>Reject</b> - Number of packets the Security Gateway rejected on this interface</li> <li>■ <b>Drop</b> - Number of packets the Security Gateway dropped on this interface</li> <li>■ <b>Accept</b> - Number of packets the Security Gateway accepted on this interface</li> <li>■ <b>Log</b> - Whether Security Gateway sends its logs from this interface (0 - no, 1 - yes)</li> </ul> |
| -s               | <p>Shows short output.</p> <p>Shows each interface and its protected traffic direction is on a separate line.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <Name of Object> | <p>Specifies the name of the Security Gateway or Cluster Member object (as defined in SmartConsole), from which to show the information. Use this parameter only on the Management Server.</p> <p>This requires the established SIC with that Check Point server.</p>                                                                                                                                                                                                                                                                                                                                                                                                                       |

### Example 1 - Default output

```
[Expert@MyGW:0]# fw stat
HOST POLICY DATE
localhost MyGW_Policy 10Sep2018 14:01:25 : [>eth0] [<eth0] [>eth1]
[Expert@MyGW:0]#
```

### Example 2 - Short output

```
[Expert@MyGW:0]# fw stat -s
HOST IF POLICY DATE
localhost >eth0 MyGW_Policy 10Sep2018 14:01:25 :
localhost <eth0 MyGW_Policy 10Sep2018 14:01:25 :
localhost >eth1 MyGW_Policy 10Sep2018 14:01:25 :
[Expert@MyGW:0]#
```

### Example 3 - Long output

```
[Expert@MyGW:0]# fw stat -l
HOST IF POLICY DATE TOTAL REJECT DROP ACCEPT LOG
localhost >eth0 MyGW_Policy 10Sep2018 14:01:25 : 14377 0 316 14061 1
localhost <eth0 MyGW_Policy 10Sep2018 14:01:25 : 60996 0 0 60996 0
localhost >eth1 MyGW_Policy 10Sep2018 14:01:25 : 304 0 304 0 0
[Expert@MyGW:0]#
```

### Example 4 - Long output from the Management Server

```
[Expert@MGMY:0]# fw stat -l MyGW
HOST IF POLICY DATE TOTAL REJECT DROP ACCEPT LOG
MyGW >eth0 MyGW_Policy 12Sep2018 16:34:56 : 120113 0 0 120113 0
MyGW <eth0 MyGW_Policy 12Sep2018 16:34:56 : 10807 0 0 10807 0
MyGW >eth2 MyGW_Policy 12Sep2018 16:34:56 : 3 0 0 3 0
MyGW <eth2 MyGW_Policy 12Sep2018 16:34:56 : 3 0 0 3 0
[Expert@MGMT:0]#
```

# fw tab

## Description

Shows data from the specified Security Gateway kernel tables.

This command also changes the content of dynamic kernel tables. You cannot change the content of static kernel tables.

Kernel tables (also known as State tables) store data that the Firewall and other Software Blades use to inspect packets. These kernel tables are a critical component of Stateful Inspection.

### ★ Best Practices:

- Use the "fw tab -t connections -f" command to see the detailed (and more technical) information about the current connections in the **Connections** kernel table (ID 8158).
- Use the "[fw ctl conntab](#)" on page 1117 command to see the simplified information about the current connections in the **Connections** kernel table (ID 8158).

### i Important:

- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- On Scalable Platforms, you must connect to the applicable Security Group.

## Syntax

```
fw tab {-h | -help}

fw [-d] tab
    -v
    -t <Table>
    {-c | -s}
    -f [-r]
    -g
    -o <Output File>
    {-u | -m <Limit>}
    -a -e "<Entry>"
    -A -e "<Entry>"
    -x [-e "<Entry>"]
    -Y
    {-z [-l] | -M}
    <Name of Object>
```

## Parameters

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d                 | <p>Runs the command in debug mode.<br/>Use only if you troubleshoot the command itself.</p> <p>★ <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p>                                                                                                                                                                                                                                                                                                    |
| -h<br>-help        | Shows the built-in usage.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| -t <Table>         | <p>Specifies the kernel table by its name of unique ID.<br/>To see the names and IDs of the available kernel tables, run:</p> <pre>fw tab -s</pre> <p>Because the output of this command is very long, we recommend to redirect it to a file. For example:</p> <pre>fw tab -s &gt; /tmp/output.txt</pre> <p><b>i Notes:</b></p> <ul style="list-style-type: none"> <li>■ If you do not specify kernel tables, then the command shows the summary data for all kernel tables.</li> <li>■ You can specify several different kernel tables in the same command.</li> </ul> |
| -a -e<br>"<Entry>" | <p>Adds the specified entry to the specified kernel table.<br/>If a kernel table has the "expire" attribute, when you add an entry with the "-a -e &lt;Entry&gt;" parameter, the new entry gets the default table timeout. You can use this parameter only locally on a Security Gateway / Cluster Member.</p> <p><b>i Important</b> - Each kernel table has its own internal format.</p> <p><b>! Warning</b> - If you add a wrong entry, you can make your Security Gateway / Cluster Member unresponsive.</p>                                                         |

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -A -e<br>"<Entry>" | <p>Adds the specified entry to the specified kernel table - in all CoreXL Firewall instances.</p> <p>If a kernel table has the "expire" attribute, when you add an entry with the "-A -e &lt;Entry&gt;" parameter, the new entry gets the default table timeout. You can use this parameter only locally on a Security Gateway / Cluster Member.</p> <p> <b>Important</b> - Each kernel table has its own internal format.</p> <p> <b>Warning</b> - If you add a wrong entry, you can make your Security Gateway / Cluster Member unresponsive.</p> |
| -c                 | <p>Shows formatted kernel table data in the common format. This is the default.</p> <p>The parameters "-c" and "-s" are mutually exclusive.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| -e<br>"<Entry>"    | <p>Specifies the entry in the kernel table.</p> <p> <b>Important</b> - Each kernel table has its own internal format.<br/>For the "Connections" (ID 8158) table, see <a href="#">sk65133</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| -f [-r]            | <p>Shows formatted kernel table data. For example, shows:</p> <ul style="list-style-type: none"> <li>■ All IP addresses and port numbers in the decimal format.</li> <li>■ All dates and times in human readable format.</li> </ul> <p>The parameter "-r" resolves IP addresses into hostnames.</p> <p> <b>Note</b> - Each table can use a different style.</p> <p> <b>Important</b> - If the specified kernel table is large, this consumes a large amount of RAM. This can make your Security Gateway unresponsive.</p>                       |
| -g                 | <p>Shows the summary data only for the Global Hash kernel tables (ghtable):</p> <pre>fw tab -g</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| -o <Output File>   | <p>Saves the output in the specified file in the CL format as a Check Point Firewall log.</p> <p>You can later open this file with the <a href="#">"fw log" on page 1167</a> command.</p> <p>If you do not specify the full path explicitly, this command saves the output file in the current working directory.</p>                                                                                                                                                                                                                                                                                                                                                                                                 |
| -m <Limit>         | <p>Specifies the maximum number of kernel table entries to show.</p> <p>This command counts the entries from the beginning of the kernel table.</p> <p>The parameters "-m" and "-u" are mutually exclusive.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -s              | Shows a short summary of the kernel table data.<br>The parameters "-s" and "-c" are mutually exclusive.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| -u              | Specifies to show an unlimited number of kernel table entries.<br>The parameters "-u" and "-m" are mutually exclusive.<br> <b>Important</b> - If the specified kernel table is large, this consumes a large amount of RAM. This can make your Security Gateway unresponsive.                                                                                                                                                                                                                                 |
| -v              | Shows the CoreXL Firewall instance number as a prefix for each line.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| -x [-e <Entry>] | Deletes all entries or the specified entry from the specified kernel table.<br>You can use this parameter only locally on a Security Gateway / Cluster Member.<br> <b>Warning</b> - We do not recommend this command for any production use, only for debugging and experimenting.<br>If you delete a wrong entry, you can break the current connections through your Security Gateway / Cluster Member.<br>This includes the remote SSH connection.<br>For more information, see <a href="#">sk103876</a> . |
| -y              | Specifies not to show a prompt before Security Gateway executes a command.<br>Applies to these parameters: "-a", "-A", and "-x".                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| -z [-l]         | In the "Connections" table (ID 8158) shows only connections in Slow Path (F2F) and the reason why acceleration is not possible for each connection. These are connections that SecureXL cannot accelerate and forwards to the Firewall.<br>The parameter "-l" shows statistics for connections.<br>The parameter "-z" implicitly runs the parameter "-u".<br>The parameters "-z" and "-M" are mutually exclusive.<br>See the corresponding example (with the legend) below.                                                                                                                   |
| -M              | In the "Connections" table (ID 8158) shows Used Memory and Peak Memory for each connection.<br>The parameter "-M" implicitly runs the parameter "-u".<br>The parameters "-M" and "-z" are mutually exclusive.<br>See the corresponding example (with the legend) below.                                                                                                                                                                                                                                                                                                                       |

| Parameter                     | Description                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>&lt;Name of Object&gt;</i> | <p>Applies only when you run this command on the Management Server.</p> <p>Specifies the name of the Security Gateway or Cluster Member object (as defined in SmartConsole), from which to show the information.</p> <p>This requires the established SIC with the Security Gateway / Cluster Member.</p> <p>If you do not use this parameter, the default is <code>localhost</code>.</p> |

## Examples

### Example 1 - Show the summary of all kernel tables

```
[Expert@MyGW:0]# fw tab -s
HOST      NAME                                     ID #VALS #PEAK #SLINKS
localhost vsx_firewalled                           0      1      1      0
localhost firewalled_list                           1      2      2      0
localhost external_firewalled_list         2      0      0      0
localhost management_list                  3      2      2      0
localhost external_management_list         4      0      0      0
localhost log_server_list                  5      0      0      0
localhost ips1_sensors_list                6      0      0      0
localhost all_tcp_services                 7     141    141      0
localhost tcp_services                     8      1      1      0
... ..
localhost connections                     8158      2     56      2
... ..
localhost up_251_rule_to_clob_uuid         14083      0      0      0
... ..
localhost urlf_cache_tbl                   29      0      0      0
localhost proxy_outbound_conn_tbl         30      0      0      0
localhost dns_cache_tbl                   31      0      0      0
localhost appi_referrer_table              32      0      0      0
localhost uc_hits_htab                     33      0      0      0
localhost uc_cache_htab                   34      0      0      0
localhost uc_incident_to_instance_htab     35      0      0      0
localhost fw_x_cntl_dyn_ghtab              36      0      0      0
localhost frag_table                       37      0      0      0
localhost dos_blacklist_notifs             38      0      0      0
[Expert@MyGW:0]#
```

**Example 2 - Show the raw data in the "Connections" table**

```
[Expert@MyGW:0]# fw tab -t connections
localhost:
----- connections -----
dynamic, id 8158, num ents 0, load factor 0.0, attributes: keep, sync, aggressive aging,

| Column      | Description                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Expires     | <p>How many seconds remain before the connection expires (based on the maximum expiration time).</p> <p>Also, refer to the "Duration" column.</p> <p>For example, 1990/3600 means:</p> <ul style="list-style-type: none"><li>▪ The maximum expiration time is 3600 seconds.</li><li>▪ If the connection remains idle for the next 1990 seconds, it expires from the Firewall "Connections" table.</li></ul> |
| Used Memory | Currently used memory for this connection.                                                                                                                                                                                                                                                                                                                                                                  |
| Peak Memory | Maximum used memory for this connection (since it was recorded).                                                                                                                                                                                                                                                                                                                                            |
| Duration    | <p>How many seconds this connection is open.</p> <p>Also, refer to the "Expires" column.</p>                                                                                                                                                                                                                                                                                                                |

# fw unloadlocal

## Description

Uninstalls all policies from the Security Gateway or Cluster Member.

### Warning:

1. The "fw unloadlocal" command prevents all traffic from passing through the Security Gateway (Cluster Member), because it disables the IP Forwarding in the Linux kernel on the Security Gateway (Cluster Member).
2. The "fw unloadlocal" command removes all policies from the Security Gateway (Cluster Member). This means that the Security Gateway (Cluster Member) accepts all incoming connections destined to all active interfaces without any filtering or protection enabled.

## Notes

- If it is necessary to remove the current policy, but keep the Security Gateway (Cluster Member) protected, then run the ["comp\\_init\\_policy" on page 964](#) command on the Security Gateway (Cluster Member).
- To load the policies on the Security Gateway (Cluster Member), run one of these commands on the Security Gateway (Cluster Member), or reboot:
  - ["fw fetch" on page 1154](#)
  - ["cpstart" on page 1032](#)
- See the related command ["fwm unload" on page 360](#).

### Important:

- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- On Scalable Platforms, use the command "asg policy unload". See the [R82.10 Scalable Platforms Administration Guide](#).

## Syntax

```
fw [-d] [-f] unloadlocal
```

## Parameters

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d        | <p>Runs the command in debug mode.</p> <p>Use only if you troubleshoot the command itself.</p> <p>★ <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p>                                                                                                                                                                               |
| -f        | <p>Uninstalls all policies only from the current VSNext Virtual Gateway / Traditional VSX Virtual System.</p> <p>Without specifying the parameter "-f", the command also disables bridge forwarding in <b>all</b> Virtual Gateways / Virtual Systems that are connected to Virtual Switches.</p> <p>As a result, traffic cannot pass through these Virtual Switches and through Virtual Gateways / Virtual Systems configured in the Bridge Mode.</p> |

## Example

```
[Expert@MyGW:0]# cpstat -f policy fw

Product name: Firewall
Policy name: My_Policy
Policy install time: Tue Oct 23 18:23:14 2018
... ..
[Expert@MyGW:0]#

[Expert@MyGW:0]# sysctl -a | grep forwarding | grep -v bridge
net.ipv6.conf.bond0.forwarding = 1
net.ipv6.conf.eth1.forwarding = 1
net.ipv6.conf.eth3.forwarding = 1
net.ipv6.conf.eth2.forwarding = 1
net.ipv6.conf.eth4.forwarding = 1
net.ipv6.conf.eth5.forwarding = 1
net.ipv6.conf.eth0.forwarding = 1
net.ipv6.conf.eth6.forwarding = 1
net.ipv6.conf.default.forwarding = 1
net.ipv6.conf.all.forwarding = 1
net.ipv6.conf.lo.forwarding = 1
net.ipv4.conf.bond0.mc_forwarding = 0
net.ipv4.conf.bond0.forwarding = 1
net.ipv4.conf.eth1.mc_forwarding = 0
net.ipv4.conf.eth1.forwarding = 1
net.ipv4.conf.eth2.mc_forwarding = 0
net.ipv4.conf.eth2.forwarding = 1
net.ipv4.conf.eth0.mc_forwarding = 0
net.ipv4.conf.eth0.forwarding = 1
net.ipv4.conf.lo.mc_forwarding = 0
net.ipv4.conf.lo.forwarding = 1
net.ipv4.conf.default.mc_forwarding = 0
net.ipv4.conf.default.forwarding = 1
net.ipv4.conf.all.mc_forwarding = 0
net.ipv4.conf.all.forwarding = 1
[Expert@MyGW:0]#

[Expert@MyGW:0]# fw unloadlocal

Uninstalling Security Policy from all.all@MyGW
Done.
[Expert@MyGW:0]#

[Expert@MyGW:0]# cpstat -f policy fw

Product name: Firewall
Policy name:
Policy install time:
... ..
[Expert@MyGW:0]#

[Expert@MyGW:0]# sysctl -a | grep forwarding | grep -v bridge
net.ipv6.conf.bond0.forwarding = 0
net.ipv6.conf.eth1.forwarding = 0
net.ipv6.conf.eth3.forwarding = 0
net.ipv6.conf.eth2.forwarding = 0
net.ipv6.conf.eth4.forwarding = 0
net.ipv6.conf.eth5.forwarding = 0
net.ipv6.conf.eth0.forwarding = 0
net.ipv6.conf.eth6.forwarding = 0
net.ipv6.conf.default.forwarding = 0
net.ipv6.conf.all.forwarding = 0
net.ipv6.conf.lo.forwarding = 0
net.ipv4.conf.bond0.mc_forwarding = 0
net.ipv4.conf.bond0.forwarding = 0
net.ipv4.conf.eth1.mc_forwarding = 0
net.ipv4.conf.eth1.forwarding = 0
net.ipv4.conf.eth2.mc_forwarding = 0
net.ipv4.conf.eth2.forwarding = 0
net.ipv4.conf.eth0.mc_forwarding = 0
net.ipv4.conf.eth0.forwarding = 0
net.ipv4.conf.lo.mc_forwarding = 0
net.ipv4.conf.lo.forwarding = 0
```

```
net.ipv4.conf.default.mc_forwarding = 0
net.ipv4.conf.default.forwarding = 0
net.ipv4.conf.all.mc_forwarding = 0
net.ipv4.conf.all.forwarding = 0
[Expert@MyGW:0]#

[Expert@MyGW:0]# fw fetch localhost
Installing Security Policy My_Policy on all.all@MyGW
Fetching Security Policy from localhost succeeded
[Expert@MyGW:0]#
```

## fw up\_execute

### Description

Executes the offline Unified Policy on the Security Gateway.

You can examine the Security Gateway behavior for the specified traffic in the current Access Control and NAT Policy.

For example, view the reason why a packet was not matched to a specified rule.

Requirement - You must install a user-defined Access Control Policy on the Security Gateway.

This tool:

1. Creates a packet based on the specified parameters.
2. Runs the current Access Control and NAT Policy on this packet.
3. Shows all the classification information.

**Note** - You can also use the Gaia API v1.8 call "`simulate-packet`". See the [Check Point Gaia API Reference](#) (at the top, select the correct version) .

**This command only supports:**

- Source IP address, Destination IP address, and objects that contain an IP address.
- Simple services objects (based on a destination port, source port, and protocol).
- Protocol detection.
- Application detection.
- First packet match.

**Explanation:**

The Security Gateway must inspect several data packets to determine an application or an involved data protocol.

If it is necessary to simulate a packet from an application or a data protocol, you must specify these explicitly in the syntax.

- TCP v4 and TCP v6 traffic (protocol #6).
- UDP v4 and UDP v6 traffic (protocol #17).
- ICMP v4 and ICMPv6 traffic (protocol #1).
- Security Zone.
- Access Roles.
- Domain Objects.
- Updatable Objects.
- Other Service, only if:
  - In the **IP Protocol** field, you configured the number of the supported protocols (TCP - 6, UDP - 17, ICMP - 1).
  - You did not configure a **Match** expression (on the **Advanced** page).
- Time Objects.

**Limitations:**

- These are not supported: DCE-RPC service, Content Awareness Software Blade, VPN traffic, Resource object, Mobile Access applications.
- NAT64 rules are not supported
- NAT46 rules are not supported
- CGNAT settings are not supported
- When you run the tool in the NAT policy mode, the tool ignores the checkbox **"Disable NAT inside the VPN community"** in the VPN Community objects.

**Important:**

- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- On Scalable Platforms, you must connect to the applicable Security Group.

**Syntax for an Access Control Rule for TCP / UDP traffic**

```
fw [-d] up_execute mode=access in_ifn=<Name of Interface> ip={6 | 11} src=<Source IP> dst=<Destination IP> [sport=<Source Port>] dport=<Destination Port> [protocol=<Protocol Detection Name>] [application="<Application/Category Name 1>" [application="<Application/Category Name 2>" ...]] [access_rule_search_uid=<Rule UID>
```

**Syntax for an Access Control Rule for ICMP traffic**

```
fw [-d] up_execute mode=access in_ifn=<Name of Interface> ip={1 | 58} src=<Source IP> dst=<Destination IP> type=<ICMP Type> code=<ICMP Code> [protocol=<Protocol Detection Name>] [application="<Application/Category Name 1>" [application="<Application/Category Name 2>" ...]] [access_rule_search_uid=<Rule UID>
```

**Syntax for a NAT Rule**

```
fw [-d] up_execute mode=nat in_ifn=<Name of Interface> ip=<IANA Protocol Number> src=<Source IP> dst=<Destination IP> [sport=<Source Port>] dport=<Destination Port>
```

**Note** - For IPv6, use the "fw6 up\_execute <parameters>" command.

## Parameters

The order of the parameters does not matter.

| Parameter                  | Description                                                                                                                                                                                                                                                                                                                                                             |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| No Parameters              | Shows the built-in usage.                                                                                                                                                                                                                                                                                                                                               |
| -d                         | <p>Runs the command in debug mode.<br/>Use only if you troubleshoot the command itself.</p> <p>★ <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p> <p>To see more information, run:<br/> <code>TDErrorr_all_all=5 fw -d &lt;parameters&gt;</code></p> |
| mode=<Rule Mode>           | <p>Specifies the rule mode:</p> <ul style="list-style-type: none"> <li>▪ mode=access - This is an Access Control rule (this is the default mode).</li> <li>▪ mode=nat - This is a NAT rule.</li> </ul>                                                                                                                                                                  |
| in_ifn=<Name of Interface> | <p>Specifies the name of the interface:</p> <ul style="list-style-type: none"> <li>▪ To simulate inbound traffic to the Security Gateway, enter the name of the interface (example: in_ifn=eth2).</li> <li>▪ To simulate outbound traffic from the Security Gateway, enter "in_ifn=localhost".</li> </ul>                                                               |
| ipp=<IANA Protocol Number> | <p>Specifies the IANA Protocol Number in the Hexadecimal format.</p> <p>Supported protocols:</p> <ul style="list-style-type: none"> <li>▪ TCP: ipp=6</li> <li>▪ UDP: ipp=17</li> <li>▪ ICMP v4: ipp=1</li> <li>▪ ICMP v6: ipp=58</li> </ul> <p>See <a href="#">IANA Protocol Numbers</a>.</p>                                                                           |
| src=<Source IP>            | <p>Optional parameter.<br/>Specifies the Source IP address.<br/>Default value: 12345.</p>                                                                                                                                                                                                                                                                               |

| <code>dport=&lt;Destination Port&gt;</code>                                | Specifies the Destination Port number in the Decimal format.<br>See <a href="#">IANA Service Name and Port Number Registry</a> .                                                                                                                                                                                                                   |
| <code>type=&lt;ICMP Type&gt;</code><br><code>code=&lt;ICMP Code&gt;</code> | Specifies the ICMP Type and ICMP Code.<br>For ICMPv4, only these pairs are supported: <ul style="list-style-type: none"> <li>▪ <code>type=8 code=0</code> - Echo Request</li> <li>▪ <code>type=0 code=0</code> - Echo Reply</li> </ul> For ICMPv6: <ul style="list-style-type: none"> <li>▪ Types 1, 2, 3, 4, and 137 are not supported</li> </ul> |
| <code>protocol=&lt;Protocol Detection Name&gt;</code>                      | Optional parameter.<br>Specifies the protocol detection name (HTTP, HTTPS, and so on), if the "Protocol Signature" option is enabled in the applicable service.                                                                                                                                                                                    |
| <code>application="&lt;Application/Category Name&gt;"</code>               | Optional parameter.<br>Specifies the name of the Application/Category as defined in SmartConsole.<br>You can specify multiple applications.<br>If the Application/Category name contains spaces, you must enclose it in double quotes (example:<br><code>application="Google Docs"</code> ).                                                       |
| <code>access_rule_search_uid=&lt;Rule UID&gt;</code>                       | Specifies the UID of an Access Control rule to examine why the packet did not match this rule.<br>In the Access Control policy, in the applicable rule, right-click the <b>No.</b> column and click <b>Copy Rule UID</b> .                                                                                                                         |

## Syntax Examples:

```
fw up_execute mode=access in_ifn=eth0 ipp=6 src=2.2.2.2
dst=1.1.1.1 dport=80 application="Facebook"
```

```
fw up_execute mode=access in_ifn=eth1 ipp=1 src=10.0.0.7
dst=1.1.1.1 type=8 code=0
```

```
fw6 up_execute mode=access in_ifn=eth1 ipp=6 src=1::7:7 dst=1::1
dport=443
```

```
fw up_execute mode=nat in_ifn=eth1 ipp=6 src=10.0.0.8 dst=1.1.1.1
dport=443
```

## Example Outputs

### Example Access Control Policy - Network Layer:

| No | Source          | Destination | VPN | Services & Applications | Action | Track | Install On     |
|----|-----------------|-------------|-----|-------------------------|--------|-------|----------------|
| 1  | United States   | MyServer    | Any | https<br>http           | Accept | None  | Policy Targets |
| 2  | MyClient        | MyNetwork   | Any | ssh                     | Drop   | None  | Policy Targets |
| 3  | .checkpoint.com | Any         | Any | Any                     | Accept | Log   | Policy Targets |
| 4  | Any             | Any         | Any | Any                     | Accept | None  | Policy Targets |

### Example Access Control Policy - Application Control Layer):

| No | Source    | Destination | VPN | Services & Applications | Action | Track | Install On     |
|----|-----------|-------------|-----|-------------------------|--------|-------|----------------|
| 1  | MyNetwork | Internet    | Any | Facebook                | Drop   | None  | Policy Targets |
| 2  | MyNetwork | Internet    | Any | Social Networking       | Drop   | None  | Policy Targets |
| 3  | Any       | Internet    | Any | Any                     | Accept | None  | Policy Targets |

## Example NAT Policy:

| No | Original Source | Original Destination | Original Services | Translated Source | Translated Destination | Translated Services | Install On     |
|----|-----------------|----------------------|-------------------|-------------------|------------------------|---------------------|----------------|
| 1  | MyClient        | MyServer             | Any               | H MyClient_NAT_IP | S MyServer_NAT_IP      | = Original          | Policy Targets |
| 2  | MyDNS1          | Any                  | Any               | = Original        | = Original             | = Original          | Policy Targets |

## Where:

- United States = An Updatable object
- MyServer = A Host object with IPv4 10.10.10.1
- MyServer\_NAT\_IP = A Host object with IPv4 194.1.1.1
- MyClient = A Host object with IPv4 192.168.1.1
- MyClient\_NAT\_IP = A Host object with IPv4 172.16.4.1
- MyNetwork = A Network object with IPv4 172.29.113.200
- .checkpoint.com = A Domain object

**Output Example 1 - Access Control - incoming traffic is matched to a user-defined rule**

```
[Expert@MyGW:0]# fw up_execute mode=access in_ifn=eth0 ipp=6 src=209.87.209.100 dst=10.10.10.1
dport=443

[Expert@MyGW:0]#
```

# fw ver

## Description

Shows this information about the Security Gateway software:

- Major version
- Minor version
- Build number
- Kernel build number

### Important:

- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- On Scalable Platforms, you must connect to the applicable Security Group.

## Syntax

```
fw [-d] ver [-k] [-f <Output File>]
```

## Parameters

| Parameter        | Description                                                                                                                                                                                                                                                             |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d               | <p>Runs the command in debug mode.</p> <p>Use only if you troubleshoot the command itself.</p> <p>★ <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p> |
| ver              | <p>Shows:</p> <ul style="list-style-type: none"><li>▪ Major version</li><li>▪ Minor version</li><li>▪ Build number</li></ul>                                                                                                                                            |
| -k               | <ul style="list-style-type: none"><li>▪ Shows:</li><li>▪ Major version</li><li>▪ Minor version</li><li>▪ Build number</li><li>▪ Kernel build number</li></ul>                                                                                                           |
| -f <Output File> | <p>Saves the output to the specified file.</p> <p>If you do not specify the full path explicitly, this command saves the output file in the current working directory.</p>                                                                                              |

## Example 1

```
[Expert@MyGW:0]# fw ver
This is Check Point's software version R82.10 - Build 123
[Expert@MyGW:0]#
```

## Example 2

```
[Expert@MyGW:0]# fw ver -k
This is Check Point's software version R82.10 - Build 123
kernel: R82.10 - Build 456
[Expert@MyGW:0]#
```

# fwboot

## Description

Configures Check Point boot options.

**Important** - Most of these commands are for Check Point use only.

## Syntax

```
[Expert@HostName:0]# $FWDIR/boot/fwboot
bootconf <options>
corexl <options>
cpuid <options>
default <options>
fwboot_ipv6 <options>
fwdefault <options>
ha_conf <options>
ht <options>
multik_reg <options>
post_drv <options>
```

## Parameters

| Parameter                | Description                                                                                                                                                   |

# fwboot bootconf

## Description

Configures boot security options.

### Notes:

- You must run this command from the Expert mode.
- The settings are saved in the `$FWDIR/boot/boot.conf` file.
  -  **Warning** - To avoid issues, do not edit the `$FWDIR/boot/boot.conf` file manually. Edit the file only with this command.
- Refer to these related commands:
  - ["fwboot corexl" on page 1304](#)
  - ["control\\_bootsec" on page 979](#)

## Syntax to show the current boot security options

```
[Expert@HostName:0]# $FWDIR/boot/fwboot bootconf
get_corexl
get_core_override
get_def
get_ipf
get_ipv6
get_kernnum
get_kern6num
```

## Syntax to configure the boot security options

```
[Expert@HostName:0]# $FWDIR/boot/fwboot bootconf
set_corexl {0 | 1}
set_core_override <number>
set_def [</path/filename>]
set_ipf {0 | 1}
set_ipv6 {0 | 1}
set_kernnum <number>
set_kern6num <number>
```

## Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                              |

# fwboot corexl

## Description

Configures and monitors the CoreXL.

**Note** - The settings are saved in the `$FWDIR/boot/boot.conf` file.

**Warning** - To avoid issues, do not edit the `$FWDIR/boot/boot.conf` file manually. Edit the file only with this command.

## Syntax to show CoreXL configuration

```
[Expert@HostName:0]# $FWDIR/boot/fwboot corexl
  core_count
  curr_instance4_count
  curr_instance6_count
  def_instance4_count
  def_instance6_count
  eligible
  installed
  max_instance4_count
  max_instances4_32bit
  max_instances4_64bit
  max_instance6_count
  max_instances_count
  max_instances_32bit
  max_instances_64bit
  min_instance_count
  unsupported_features
```

## Syntax to configure CoreXL

### Important:

- The configuration commands are for Check Point use only. To configure CoreXL, use the **Check Point CoreXL** option in the ["cpconfig" on page 1002](#) menu.
- After all changes in CoreXL configuration on the Security Gateway, you must reboot it.
- In a Cluster, you must configure all the Cluster Members in the same way.

```
[Expert@HostName:0]# $FWDIR/boot/fwboot corexl
def_by_allowed [n]
default
[-v] disable
[-v] enable [n] [-6 k]
vmalloc_recalculate
```

## Parameters

| Parameter     | Description                                                                                                                                                                                                                                                                                                              |

# fwboot cpuid

## Description

Shows the number of available CPUs and CPU cores on this Security Gateway.

## Syntax

```
[Expert@HostName:0]# $FWDIR/boot/fwboot cpuid
    {-h | -help | --help}
    -c
    --full
    ht_aware
    -n
    --possible
```

## Parameters

| Parameter     | Description                                                                                                                                                                                                                                                    |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| No Parameters | <p>Shows the IDs of the available CPU cores on this Security Gateway.</p> <p><b>Example</b></p> <pre>[Expert@MyGW:0]# \$FWDIR/boot/fwboot cpuid 3 2 1 0 [Expert@MyGW:0]#</pre>                                                                                 |
| -c            | <p>Counts the number of available CPU cores on this Security Gateway. The command stores the returned number as its exit code.</p> <p><b>Example</b></p> <pre>[Expert@MyGW:0]# \$FWDIR/boot/fwboot cpuid -c [Expert@MyGW:0]# echo \$? 4 [Expert@MyGW:0]#</pre> |

| Parameter               | Description                                                                                                                                                                                                                                               |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--full</code>     | <p>Shows a full map of the available CPUs and CPU cores on this Security Gateway.</p> <p><b>Example</b></p> <pre>[Expert@MyGW:0]# \$FWDIR/boot/fwboot cpuid --full cpuid phys_id core_id thread_id 0 0 0 0 1 2 0 0 2 4 0 0 3 6 0 0 [Expert@MyGW:0]#</pre> |
| <code>ht_aware</code>   | <p>Shows the CPU cores in the order of their awareness of Hyper-Threading.</p> <p><b>Example</b></p> <pre>[Expert@MyGW:0]# \$FWDIR/boot/fwboot cpuid ht_aware 3 2 1 0 [Expert@MyGW:0]#</pre>                                                              |
| <code>-n</code>         | <p>Counts the number of available CPUs on this Security Gateway. The command stores the returned number as its exit code.</p> <p><b>Example</b></p> <pre>[Expert@MyGW:0]# \$FWDIR/boot/fwboot cpuid -n [Expert@MyGW:0]# echo \$? 4 [Expert@MyGW:0]#</pre> |
| <code>--possible</code> | <p>Counts the number of possible CPU cores. The command stores the returned number as its exit code.</p> <p><b>Example</b></p> <pre>[Expert@MyGW:0]# \$FWDIR/boot/fwboot cpuid --possible [Expert@MyGW:0]# echo \$? 4 [Expert@MyGW:0]#</pre>              |

# fwboot default

## Description

Loads the specified Default Filter policy on this Security Gateway.

## Notes:

- You must run this command from the Expert mode.
- This command is the same as the ["fwboot fwdefault" on page 1315](#) command.
- Refer to these related commands:
  - ["fw defaultgen" on page 1152](#)
  - ["fwboot bootconf" on page 1300](#)
  - ["control\\_bootsec" on page 979](#)
  - ["comp\\_init\\_policy" on page 964](#)

## Syntax

```
[Expert@HostName:0]# $FWDIR/boot/fwboot default <Default Filter Policy File>
```

## Parameters

| Parameter                    | Description                                                                                                    |
|------------------------------|----------------------------------------------------------------------------------------------------------------|
| No Parameters                | Shows the built-in help with available parameters.                                                             |
| <Default Filter Policy File> | Specifies the full path and name of the Default Filter policy file.<br>The default is \$FWDIR/boot/default.bin |

## Example

```
[Expert@MyGW:0]# $FWDIR/boot/fwboot default $FWDIR/boot/default.bin
FW-1: Default filter installed successfully
[Expert@MyGW:0]#
[Expert@MyGW:0]# fw stat
HOST POLICY DATE
localhost defaultfilter 13Sep2018 14:27:23 : [>eth0] [<eth0]
[Expert@MyGW:0]
```

# fwboot fwboot\_ipv6

## Description

Shows the internal memory address of the hook function for the specified CoreXL Firewall instance.

 **Important** - This command is for Check Point use only.

## Syntax

```
[Expert@HostName:0]# $FWDIR/boot/fwboot fwboot_ipv6 <Number of CoreXL Firewall instance> hook [-d]
```

## Parameters

| Parameter                            | Description                                              |
|--------------------------------------|----------------------------------------------------------|
| No Parameters                        | Shows the built-in help with available parameters.       |
| <Number of CoreXL Firewall instance> | Specifies the ID number of the CoreXL Firewall instance. |
| -d                                   | Shows the decimal 64-bit address of the hook function.   |

## Example

```
[Expert@MyGW:0]# fw ctl multik stat
ID | Active | CPU | Connections | Peak
-----
0 | Yes | 3 | 11 | 18
1 | Yes | 2 | 12 | 18
2 | Yes | 1 | 13 | 18
[Expert@MyGW:0]#

[Expert@MyGW:0]# $FWDIR/boot/fwboot fwboot_ipv6 0 hook
0xfffffffff89f8fc00
[Expert@MyGW:0]#

[Expert@MyGW:0]# $FWDIR/boot/fwboot fwboot_ipv6 1 hook
0xfffffffff8cd71c00
[Expert@MyGW:0]#

[Expert@MyGW:0]# $FWDIR/boot/fwboot fwboot_ipv6 2 hook
0xfffffffff8fb53c00
[Expert@MyGW:0]#
```

# fwboot fwdefault

## Description

Loads the specified Default Filter policy on this Security Gateway.

### Notes:

- You must run this command from the Expert mode.
- This command is the same as the ["fwboot default" on page 1313](#) command.
- Refer to these related commands:
  - ["fw defaultgen" on page 1152](#)
  - ["fwboot bootconf" on page 1300](#)
  - ["control\\_bootsec" on page 979](#)
  - ["comp\\_init\\_policy" on page 964](#)

## Syntax

```
[Expert@HostName:0]# $FWDIR/boot/fwboot fwdefault <Default Filter Policy File>
```

## Parameters

| Parameter                                 | Description                                                                                                                      |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| No Parameters                             | Shows the built-in help with available parameters.                                                                               |
| <i>&lt;Default Filter Policy File&gt;</i> | Specifies the full path and name of the Default Filter policy file.<br>The default file is <code>\$FWDIR/boot/default.bin</code> |

## Example

```
[Expert@MyGW:0]# $FWDIR/boot/fwboot fwdefault $FWDIR/boot/default.bin
FW-1: Default filter installed successfully
[Expert@MyGW:0]#
[Expert@MyGW:0]# fw stat
HOST POLICY DATE
localhost defaultfilter 13Sep2018 14:27:23 : [>eth0] [<eth0]
[Expert@MyGW:0]
```

# fwboot ha\_conf

## Description

Configures the cluster mechanism during boot.

**Important** - This command is for Check Point use only.

### Notes:

- You must run this command from the Expert mode.
- Refer to these related commands:
  - ["fw defaultgen" on page 1152](#)
  - ["fwboot bootconf" on page 1300](#)
  - ["control\\_bootsec" on page 979](#)
  - ["comp\\_init\\_policy" on page 964](#)
- To install a cluster, see the [R82.10 Installation and Upgrade Guide](#).
- To configure a cluster, see the [R82.10 Installation and Upgrade Guide](#) and [R82.10 ClusterXL Administration Guide](#).

## Syntax

```
[Expert@HostName:0]# $FWDIR/boot/fwboot ha_conf
```

## fwboot ht

 **Important** - This command is obsolete and is not supported. To configure SMT (HyperThreading) feature, follow [sk93000](#).

# fwboot multik\_reg

## Description

Shows the internal memory address of the registration function for the specified CoreXL Firewall instance.

**Important** - This command is for Check Point use only.

**Note** - You must run this command from the Expert mode.

## Syntax

```
[Expert@HostName:0]# $FWDIR/boot/fwboot multik_reg <Number of  
CoreXL Firewall instance> {ipv4 | ipv6} [-d]
```

## Parameters

| Parameter                                         | Description                                              |
|---------------------------------------------------|----------------------------------------------------------|
| No Parameters                                     | Shows the built-in help with available parameters.       |
| <i>&lt;Number of CoreXL Firewall instance&gt;</i> | Specifies the ID number of the CoreXL Firewall instance. |
| ipv4                                              | Specifies to work with IPv4 CoreXL Firewall instances.   |
| ipv6                                              | Specifies to work with IPv6 CoreXL Firewall instances.   |
| -d                                                | Shows the decimal 64-bit address of the hook function.   |

## Example

```
[Expert@MyGW:0]# fw ctl multik stat
ID | Active | CPU | Connections | Peak
-----
0 | Yes | 3 | 11 | 18
1 | Yes | 2 | 12 | 18
2 | Yes | 1 | 13 | 18
[Expert@MyGW:0]#

[Expert@MyGW:0]# $FWDIR/boot/fwboot multik_reg 0 ipv4
0
[Expert@MyGW:0]#

[Expert@MyGW:0]# $FWDIR/boot/fwboot multik_reg 1 ipv4
0xffffffff8a2a5690
[Expert@MyGW:0]#

[Expert@MyGW:0]# $FWDIR/boot/fwboot multik_reg 2 ipv4
0xffffffff8a2a5690
[Expert@MyGW:0]#
```

# fwboot post\_drv

## Description

Loads the Firewall driver for CoreXL during boot.

 **Important:**

- This command is for Check Point use only.
- If you run this command, Security Gateway can block all traffic. In such case, you must connect to the Security Gateway over a console and restart Check Point services with the ["cpstop" on page 1043](#) and ["cpstart" on page 1032](#) commands. Alternatively, you can reboot the Security Gateway.

 **Note** - You must run this command from the Expert mode.

## Syntax

```
[Expert@HostName:0]# $FWDIR/boot/fwboot post_drv {ipv4 | ipv6}
```

## Parameters

| Parameter     | Description                                        |
|---------------|----------------------------------------------------|
| No Parameters | Shows the built-in help with available parameters. |
| ipv4          | Loads the IPv4 Firewall driver for CoreXL.         |
| ipv6          | Loads the IPv6 Firewall driver for CoreXL.         |

# fwmode

## Description

Shows and configures the Firewall mode - User Space Firewall (USFW) and Kernel Space Firewall (KSFw).

### Important:

- To configure the Firewall mode, use the "cpconfig" command as described in [sk167052](#).
- You must run this command in the Expert mode.
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the Gaia Portal of the applicable Security Group.

## Syntax

```
fwmode
    -h
    -i
    {-k | -u} [-r] [-q]
    -s
```

## Parameters

| Step         | Instructions                                                       |
|--------------|--------------------------------------------------------------------|
| No Parameter | Shows the available parameters.                                    |
| -h           | Shows the complete built-in help.                                  |
| -i           | Shows if a reboot is required after you changed the Firewall mode. |
| -k           | Configures the Kernel Space Firewall (KSFw) mode.                  |
| -q           | Quiet mode - does not print messages on the screen.                |
| -r           | Forces the immediate reboot after the change.                      |
| -s           | Shows the current Firewall mode.                                   |
| -u           | Configures the User Space Firewall (USFW) mode.                    |

## Example

```
[Expert@MyGW:0]# fwmode -s  
Firewall is Kernel mode  
[Expert@MyGW:0]#
```

# ioc\_feeder

## Description

After you configure Custom Intelligence Feeds (Indicators of Compromise, IoC) as described in [sk132193](#), you can use this command for troubleshooting purposes to fetch the configured IoC Feeds.

In addition, see:

- ["ioc\\_feeds" on page 1324](#)
- ["ioc\\_search" on page 1325](#)

### Important:

- You must run this command in the Expert mode.
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the Gaia Portal of the applicable Security Group.

## Procedure

1. Connect to the command line on the Security Gateway / Cluster Member / Scalable Platform Security Group.
2. Log in to the Expert mode.
3. Rotate the current log file:

```
mv -v $FWDIR/log/ioc_feeder.elg{,_BKP}
```

4. Fetch IoC Feeds in the debug mode (this command does not show any output):

```
$FWDIR/bin/ioc_feeder -d -f
```

5. Example this log file on the Security Gateway / Cluster Member / Scalable Platform Security Group:

```
$FWDIR/log/ioc_feeder.elg
```

# ioc\_feeds

## Description

Shows and configures Custom Intelligence Feeds (Indicators of Compromise, IoC). See [sk132193](#).

In addition, see:

- ["ioc\\_search" on page 1325](#)
- ["ioc\\_feeder" on page 1323](#)

### Important:

- You must run this command in the Expert mode.
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the Gaia Portal of the applicable Security Group.

## Syntax

```
ioc_feeds {-h | --help}
```

# ioc\_search

## Description

After you configure Custom Intelligence Feeds (Indicators of Compromise, IoC) as described in [sk132193](#), you can use this command to check if an observable from external IoC feeds was loaded correctly. This command shows the components that are related to the specific observable type.

In addition, see:

- ["ioc\\_feeds" on page 1324](#)
- ["ioc\\_feeder" on page 1323](#)

### Important:

- You must run this command in the Expert mode.
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the Gaia Portal of the applicable Security Group.

## Syntax

```
ioc_search {ip | hash | snort | mail | url | domain} <Value>
```

# sam\_alert

## Description

For SAM v1, this utility executes Suspicious Activity Monitoring (SAM) actions according to the information received from the standard input.

For SAM v2, this utility executes Suspicious Activity Monitoring (SAM) actions with User Defined Alerts mechanism.

### Important:

- You must run this command on the Management Server.
- You can run this command only in the Expert mode.
- On a Multi-Domain Server, you must run this command in the context of the applicable Domain Management Server:

```
mdsend <IP Address or Name of Domain Management Server>
```

### Notes:

- VSX Gateways and VSX Cluster Members do **not** support Suspicious Activity Monitoring (SAM) Rules. See [sk79700](#).
- See the ["fw sam" on page 295](#) and ["fw sam\\_policy" on page 303](#) commands.

## SAM v1 syntax

```
sam_alert [-v] [-o] [-s <SAM Server>] [-t <Time>] [-f <Security Gateway>] [-C] {-n|-i|-I} {-src|-dst|-any|-srv}
```

## Parameters for SAM v1

| Parameter       | Description                                                                                           |
|-----------------|-------------------------------------------------------------------------------------------------------|
| -v              | Enables the verbose mode for the "fw sam" command.                                                    |
| -o              | Specifies to print the input of this tool to the standard output (to use with pipes in a CLI syntax). |
| -s <SAM Server> | Specifies the SAM Server to be contacted. Default is "localhost".                                     |
| -t <Time>       | Specifies the time (in seconds), during which to enforce the action. The default is forever.          |

| Parameter                | Description                                                                                                                                                                                                                                                                                                                                |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -f<br><Security Gateway> | Specifies the Security Gateway / Cluster object, on which to run the operation.<br> <b>Important</b> - If you do not specify the target Security Gateway / Cluster object explicitly, this command applies to all managed Security Gateways and Clusters. |
| -C                       | Cancels the specified operation.                                                                                                                                                                                                                                                                                                           |
| -n                       | Specifies to notify every time a connection, which matches the specified criteria, passes through the Security Gateway / ClusterXL / Security Group.                                                                                                                                                                                       |
| -i                       | Inhibits (drops or rejects) connections that match the specified criteria.                                                                                                                                                                                                                                                                 |
| -I                       | Inhibits (drops or rejects) connections that match the specified criteria and closes all existing connections that match the specified criteria.                                                                                                                                                                                           |
| -src                     | Matches the source address of connections.                                                                                                                                                                                                                                                                                                 |
| -dst                     | Matches the destination address of connections.                                                                                                                                                                                                                                                                                            |
| -any                     | Matches either the source or destination address of connections.                                                                                                                                                                                                                                                                           |
| -srv                     | Matches specific source, destination, protocol and port.                                                                                                                                                                                                                                                                                   |

## SAM v2 syntax

```
sam_alert -v2 [-v] [-O] [-S <SAM Server>] [-t <Time>] [-f
<Security Gateway>] [-n <Name>] [-c "<Comment>"] [-o
<Originator>] [-l {r | a}] -a {d | r | n | b | q | i} [-C] {-ip
|-eth} {-src|-dst|-any|-srv}
```

## Parameters for SAM v2

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                  |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -v2                   | Specifies to use SAM v2.                                                                                                                                                                                                                                                                                                                     |
| -v                    | Enables the verbose mode for the "fw sam" command.                                                                                                                                                                                                                                                                                           |
| -O                    | Specifies to print the input of this tool to the standard output (to use with pipes in a CLI syntax).                                                                                                                                                                                                                                        |
| -S <SAM Server>       | Specifies the SAM server to be contacted. Default is "localhost".                                                                                                                                                                                                                                                                            |
| -t <Time>             | Specifies the time (in seconds), during which to enforce the action. The default is forever.                                                                                                                                                                                                                                                 |
| -f <Security Gateway> | Specifies the Security Gateway / Cluster object, on which to run the operation.<br> <b>Important</b> - If you do not specify the target Security Gateway / Cluster object explicitly, this command applies to all managed Security Gateways and Clusters. |
| -n <Name>             | Specifies the name for the SAM rule.<br>Default is empty.                                                                                                                                                                                                                                                                                    |
| -c "<Comment>"        | Specifies the comment for the SAM rule.<br>Default is empty.<br>You must enclose the text in the double quotes or single quotes.                                                                                                                                                                                                             |
| -o <Originator>       | Specifies the originator for the SAM rule.<br>Default is "sam_alert".                                                                                                                                                                                                                                                                        |

| Parameter                               | Description                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-l {r   a}</code>                 | <p>Specifies the log type for connections that match the specified criteria:</p> <ul style="list-style-type: none"> <li>▪ <code>r</code> - Regular</li> <li>▪ <code>a</code> - Alert</li> </ul> <p>Default is <code>None</code>.</p>                                                                                                                 |
| <code>-a {d   r   n   b   q   i}</code> | <p>Specifies the action to apply on connections that match the specified criteria:</p> <ul style="list-style-type: none"> <li>▪ <code>d</code> - Drop</li> <li>▪ <code>r</code> - Reject</li> <li>▪ <code>n</code> - Notify</li> <li>▪ <code>b</code> - Bypass</li> <li>▪ <code>q</code> - Quarantine</li> <li>▪ <code>i</code> - Inspect</li> </ul> |
| <code>-C</code>                         | Specifies to close all existing connections that match the criteria.                                                                                                                                                                                                                                                                                 |
| <code>-ip</code>                        | Specifies to use IP addresses as criteria parameters.                                                                                                                                                                                                                                                                                                |
| <code>-eth</code>                       | Specifies to use MAC addresses as criteria parameters.                                                                                                                                                                                                                                                                                               |
| <code>-src</code>                       | Matches the source address of connections.                                                                                                                                                                                                                                                                                                           |
| <code>-dst</code>                       | Matches the destination address of connections.                                                                                                                                                                                                                                                                                                      |
| <code>-any</code>                       | Matches either the source or destination address of connections.                                                                                                                                                                                                                                                                                     |
| <code>-srv</code>                       | Matches specific source, destination, protocol and port.                                                                                                                                                                                                                                                                                             |

## Example

See [sk110873: How to configure Security Gateway to detect and prevent port scan.](#)

# stattest

## Description

Check Point AMON client to query SNMP OIDs.

You can use this command as an alternative to the standard SNMP commands for debug purposes - to make sure the applicable SNMP OIDs provide the requested information.

### Notes:

- You can run this command only in the Expert mode.
- On a Multi-Domain Server, you must run this command in the context of the applicable Domain Management Server:

```
mdsenv <IP Address or Name of Domain Management Server>
```

## Syntax to query a Regular OID

- On a Management Server / Security Gateway / Cluster Member:

```
stattest get [-d] [-h <Host>] [-p <Port>] [-x <Proxy Server>] [-v <VSID>] [-t <Timeout>] <Regular_OID_1> <Regular_OID_2> ...  
<Regular_OID_N>
```

- On a Scalable Platform Security Group:

```
g_all stattest get [-d] [-h <Host>] [-p <Port>] [-x <Proxy Server>] [-v <VSID>] [-t <Timeout>] <Regular_OID_1> <Regular_OID_2>  
... <Regular_OID_N>
```

### Notes:

- These Regular OIDs are specified in the SNMP MIB files.
- For Check Point MIB files, see [sk90470](#).

## Syntax to query a Statistical OID

- On a Management Server / Security Gateway / Cluster Member:

```
stattest get [-d] [-h <Host>] [-p <Port>] [-x <Proxy Server>] -l <Polling Interval> -r <Polling Duration> [-v <VSID>] [-t <Timeout>] <Statistical_OID_1> <Statistical_OID_2> ... <Statistical_OID_N>
```

- On a Scalable Platform Security Group:

```
g_all stattest get [-d] [-h <Host>] [-p <Port>] [-x <Proxy Server>] -l <Polling Interval> -r <Polling Duration> [-v <VSID>] [-t <Timeout>] <Statistical_OID_1> <Statistical_OID_2> ... <Statistical_OID_N>
```

### Notes:

- These Statistical OIDs take some time to "initialize".
- For example, to calculate an average, it is necessary to collect enough samples.
- Check Point statistical OIDs are registered in the `$CPDIR/conf/statistical_oid.conf` file.

### Parameters

| Parameter                                | Description                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-d</code>                          | <p>Runs the command in debug mode. Use only if you troubleshoot the command itself.</p> <p> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p> |
| <code>-h &lt;Host&gt;</code>             | Specifies the remote Check Point host to query by its IP address or resolvable hostname.                                                                                                                                                                                                                                                           |
| <code>-p &lt;Port&gt;</code>             | Specifies the port number, on which the AMON server listens. Default port is 18192.                                                                                                                                                                                                                                                                |
| <code>-x &lt;Proxy Server&gt;</code>     | <p>Specifies the Proxy Server by its IP address or resolvable hostname.</p> <p> <b>Note</b> - Use only when you query a remote host.</p>                                                                                                                        |
| <code>-l &lt;Polling Interval&gt;</code> | <p>Specifies the time in seconds between queries.</p> <p> <b>Note</b> - Use only when you query a Statistical OID.</p>                                                                                                                                          |

| Parameter                                                                                              | Description                                                                                                                                                                                                                                                                                                           |
|--------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| <code>-v &lt;VSID&gt;</code>                                                                           | On a VSX Gateway, specifies the context of a Virtual Device to query.                                                                                                                                                                                                                                                 |
| <code>-t &lt;Timeout&gt;</code>                                                                        | Specifies the session timeout in milliseconds.                                                                                                                                                                                                                                                                        |
| <code>&lt;Regular_OID_1&gt; &lt;Regular_OID_2&gt;<br/>... &lt;Regular_OID_N&gt;</code>                 | Specifies the Regular OIDs to query.<br> <b>Notes:</b> <ul style="list-style-type: none"> <li>▪ OID must not start with period.</li> <li>▪ Separate the OIDs with spaces.</li> <li>▪ You can specify up to 100 OIDs.</li> </ul>      |
| <code>&lt;Statistical_OID_1&gt;<br/>&lt;Statistical_OID_2&gt; ...<br/>&lt;Statistical_OID_N&gt;</code> | Specifies the Statistical OIDs to query.<br> <b>Notes:</b> <ul style="list-style-type: none"> <li>▪ OID must not start with period.</li> <li>▪ Separate the OIDs with spaces.</li> <li>▪ You can specify up to 100 OIDs.</li> </ul> |

### Example - Query a Regular OID

Query the CPU Idle utilization at the OID 1.3.6.1.4.1.2620.1.6.7.2.3 (`procIdleTime`).

```
[Expert@HostName]# stattest get 1.3.6.1.4.1.2620.1.6.7.4.2
```

### Example - Query a Statistical OID

Query the CPU Idle utilization at the OID 1.3.6.1.4.1.2620.1.6.7.2.3 (`procIdleTime`).

Information is collected with intervals of 5 seconds during 5 seconds

```
[Expert@HostName]# stattest get -l 5 -r 5 1.3.6.1.4.1.2620.1.6.7.2.3
```

# tp\_collector\_cli

## Description

This is a light debug tool that runs in the background on the Security Gateways. The tool automatically collects information about the main points in Threat Prevention for each traffic flow.

For any issue, you can examine the "tp\_collector\_cli" output to understand what was the connection flow and understand the area of the issue.

### Notes:

- You can run this command in the Expert mode.
- On Scalable Platforms, you must connect to the Gaia Portal of the applicable Security Group.
- On a VSNext Gateway / Legacy VSX Gateway, you must run this command in the context of the applicable Virtual Gateway / Virtual System:

```
vsenv <ID>
```

- This tool saves its history data in the `$FWDIR/log/tp_collector.dat` file.
- This tool saves its log (failures it finds in connections) in the `$FWDIR/log/tp_failures.elg` file.

## Syntax for the Expert mode

```
[Expert@GW:0]# tp_collector_cli {-h | --help}
```

```
[Expert@GW:0]# tp_collector_cli
    [--filter <Filter Name 1> [{not^ | contains%}]<Filter Value
1> [<Filter Name 2> [{not^ | contains%}]<Filter Value 2>] ...
[<Filter Name N> {not^}{contains%}<Filter Value N>]]
    [--delim "<Delimiter>"]
    [--input_file <Path>]
    [--last_minutes <Number>]
    [--print_key_names]
```

## Parameters

| Parameter                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <code>--last_minutes<br/>&lt;Number&gt;</code>    | <p>Optional.</p> <p>Specifies the number of last minutes, for which to show the information from the data file.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Example output of one record:**

```

Time:06/21 09:45:06
Instance:0
Conn:dir 0, 192.168.22.33:45678 -> 172.16.44.55:80 IPP 6
Session:1933
App:CI_AV
File Name:test.deb
Content-Length:8144
Strict Hold:1
Last Buffer Seen:1
rule_id:4
profile_id:1
AV Performed Hold:09:45:06
Accumulated File Size:8144
RAD Verdict:ACCEPT
File Type ID:1100
File MD5:8add8c310e05a8a5243414ef669f19bc
AV Async Response Time:09:45:06
AV Verdict:ACCEPT
Final Action:ACCEPT
Final Async Action Time:09:45:06
Strict Hold Start Sending File:1

```

**Example filter 1 - filtering for the application "CI\_AV" for the last 5 minutes:**

```
tp_collector_cli --filter "App" CI_AV --last_minutes 5
```

**Example filter 2 - filtering for the specified time frame:**

```
tp_collector_cli --filter "Time_start" "06/21 09:40:00" "Time_end" "06/21 09:50:00"
```

```
tp_collector_cli --filter "Time_start" contains%"06/21 09"
```

**Example filter 3 - filtering for a specific connection:**

You can only filter using the full connection tuple.

```
tp_collector_cli --filter "Conn" "dir 0, 192.168.22.33:45678 -> 172.16.44.55:80 IPP 6"
```

# usrchk

## Description

Controls the UserCheck daemon (*usrchkd*).

## Syntax on a Security Gateway / Cluster Member in Gaia Clish or the Expert mode

```
usrchk
  hits <options>
  incidents <options>
  debug <options>
```

## Syntax on a Scalable Platform Security Group in Gaia gClish

```
usrchk
  hits <options>
  incidents <options>
  debug <options>
```

## Syntax on a Scalable Platform Security Group in the Expert mode

```
g_all usrchk
  hits <options>
  incidents <options>
  debug <options>
```

**Note** - You can also enter partial names of the sub-commands and their options.

## Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

### Notes:

- To show all UserCheck objects, run:

```
usrchk hits list all
```

- You can run a command that contains "`user <UserName>`" only if:
  - Identity Awareness is enabled on the Security Gateway.
  - User object is used in the same policy rules as UserCheck objects.

# ClusterXL Commands

For more information about Check Point cluster, see the [R82.10 ClusterXL Administration Guide](#).

# ClusterXL Configuration Commands

## Description

These commands let you configure internal behavior of the Clustering Mechanism.

### Important:

- We do not recommend that you run these commands. These commands must be run automatically only by the Security Gateway or the Check Point Support.
- In a Cluster, you must configure all the Cluster Members in the same way.

## Syntax

### Notes:

- In Gaia Clish:  
Enter the `set cluster<ESC><ESC>` to see all the available commands.
- In Expert mode:  
Run the `cphaconf` command see all the available commands.  
You can run the `cphaconf` commands only from the Expert mode.
- Syntax legend:
  1. Curly brackets or braces `{ }`:  
Enclose a list of available commands or parameters, separated by the vertical bar `|`, from which user can enter only one.
  2. Angle brackets `< >`:  
Enclose a variable - a supported value user needs to specify explicitly.
  3. Square brackets or brackets `[ ]`:  
Enclose an optional command or parameter, which user can also enter.
- You can include these commands in scripts to run them automatically.  
The meaning of each command is explained in the next sections.

Table: ClusterXL Configuration Commands

| Description of Command                                                                                                                                                                            | Command in Gaia Clish                              | Command in Expert Mode                        |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|-----------------------------------------------|
| Configure how to show the Cluster Member in local ClusterXL logs - by its Member ID or its Member Name (see <a href="#">"Configuring the Cluster Member ID Mode in Local Logs" on page 1346</a> ) | <code>set cluster member idmode {id   name}</code> | <code>cphaconf mem_id_mode {id   name}</code> |

| Description of Command                                                                                                                                                      | Command in Gaia Clish                               | Command in Expert Mode                                                                                                    |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------|
| Register a single Critical Device (Pnote) on the Cluster Member (see <a href="#">"Registering a Critical Device" on page 1347</a> )                                         | N / A                                               | <pre>cphaconf set_pnote -d &lt;Name of Device&gt; -t &lt;Timeout in Sec&gt; -s {ok init problem} [-p] [-g] register</pre> |
| Unregister a single Critical Device (Pnote) on the Cluster Member (see <a href="#">"Unregistering a Critical Device" on page 1351</a> )                                     | N / A                                               | <pre>cphaconf set_pnote -d &lt;Name of Device&gt; [-p] [-g] unregister</pre>                                              |
| Report (change) a state in a single Critical Device (Pnote) on the Cluster Member (see <a href="#">"Reporting the State of a Critical Device" on page 1352</a> )            | N / A                                               | <pre>cphaconf set_pnote -d &lt;Name of Device&gt; -s {ok init problem} [-g] report</pre>                                  |
| Register several Critical Devices (Pnotes) from a file on the Cluster Member (see <a href="#">"Registering Critical Devices Listed in a File" on page 1354</a> )            | N / A                                               | <pre>cphaconf set_pnote -f &lt;Name of File&gt; [-g] register</pre>                                                       |
| Unregister all Critical Devices (Pnotes) on the Cluster Member (see <a href="#">"Unregistering All Critical Devices" on page 1356</a> )                                     | N / A                                               | <pre>cphaconf set_pnote -a [-g] unregister</pre>                                                                          |
| Configure the Cluster Control Protocol (CCP) Encryption on the Cluster Member (see <a href="#">"Configuring the Cluster Control Protocol (CCP) Settings" on page 1357</a> ) | <pre>set cluster member ccpenc {off   on}</pre>     | <pre>cphaconf ccp_ encrypt {off   on} cphaconf ccp_ encrypt_key &lt;Key String&gt;</pre>                                  |
| Configure the Cluster Forwarding Layer on the Cluster Member (controls the forwarding of traffic between Cluster Members)<br><b>Note</b> - For Check Point use only.        | <pre>set cluster member forwarding {off   on}</pre> | <pre>cphaconf forward {off   on}</pre>                                                                                    |
| Print the current cluster configuration as loaded in the kernel on the Cluster Member (for details, see <a href="#">sk93306</a> )                                           | N / A                                               | <pre>cphaconf debug_data</pre>                                                                                            |

Table: ClusterXL Configuration Commands (continued)

| Description of Command                                                                                                                                                                                              | Command in Gaia Clish                                                                        | Command in Expert Mode                                                                         |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------|
| Start internal failover between subordinate interfaces of specified bond interface - only in Bond High Availability mode (for details, see <a href="#">sk93306</a> )                                                | N / A                                                                                        | <code>cphaconf failover_bond &lt;bond_name&gt;</code>                                          |
| Configure what happens during a failover after a Bond already failed over internally (for details, see <a href="#">sk93306</a> )                                                                                    | N / A                                                                                        | <code>cphaconf enable_bond_failover &lt;bond_name&gt;</code>                                   |
| Initiate manual cluster failover (see <a href="#">"Initiating Manual Cluster Failover" on page 1358</a> )                                                                                                           | <code>set cluster member admin {down   up}</code>                                            | <code>clusterXL_admin {down   up}</code>                                                       |
| Configure the minimum number of required subordinate interfaces for Bond Load Sharing (see <a href="#">"Configuring the Minimum Number of Required Subordinate Interfaces for Bond Load Sharing" on page 1362</a> ) | <code>set interface &lt;Bond Name&gt; links &lt;Value&gt;</code>                             | <code>cphaconf bond_ls {set &lt;Bond Name&gt; &lt;Value&gt;   remove &lt;Bond Name&gt;}</code> |
| Configuring Link Monitoring on the Cluster Interfaces (see <a href="#">"Configuring Link Monitoring on the Cluster Interfaces" on page 1365</a> )                                                                   | N / A                                                                                        | N / A                                                                                          |
| Configuring the Multi-Version Cluster Mechanism (see <a href="#">"Configuring the Multi-Version Cluster Mechanism" on page 1368</a> )                                                                               | N / A                                                                                        | <code>cphaconf mvc {off   on}</code>                                                           |
| Configuring duration of forced cluster failover in the High Availability mode (see <a href="#">"Configuring Duration of Forced Failover in High Availability Mode" on page 1369</a> )                               | <code>set cluster force_failover member_id &lt;ID&gt; {time &lt;Minutes&gt; on   off}</code> | <code>cphaconf force_failover member_id &lt;ID&gt; {time &lt;Minutes&gt; on   off}</code>      |

## List of the Gaia Clish "set cluster" commands

```
set cluster member admin {down | up} [permanent]
set cluster member ccpenc {off | on}
set cluster member forwarding {off | on}
set cluster member idmode {id | name}
set cluster member mvc {off | on}
set cluster force_failover member_id <ID> {time <Minutes> on | off}
```

## List of the Expert mode "cphaconf" commands

**Note** - Some commands are not applicable to 3rd-party clusters.

```
cphaconf [-D] <options> start
cphaconf stop
cphaconf [-t <Sync IF 1>...] [-d <Non-Monitored IF 1>...] add
cphaconf clear-secured
cphaconf clear-non-monitored
cphaconf debug_data
cphaconf delete_link_local [-vs <VSID>] <IF name>
cphaconf set_link_local [-vs <VSID>] <IF name> <Cluster IP>
cphaconf mem_id_mode {id | name}
cphaconf failover_bond <bond_name>
cphaconf [-s] {set | unset | get} var <Kernel Parameter Name>
[<Value>]
cphaconf bond_ls {set <Bond Name> <Value> | remove <Bond Name>}
cphaconf set_pnote -d <Device> -t <Timeout in sec> -s {ok | init | problem} [-p] [-g] register
cphaconf set_pnote -f <File> [-g] register
cphaconf set_pnote -d <Device> [-p] [-g] unregister
cphaconf set_pnote -a [-g] unregister
cphaconf set_pnote -d <Device> -s {ok | init | problem} [-g] report
cphaconf ccp_encrypt {off | on}
cphaconf ccp_encrypt_key <Key String>
cphaconf mvc {on | off}
cphaconf force_failover member_id <ID> {time <Minutes> on | off}
cphaconf vs_monitor -vs {all | <VSID1>,<VSID2>,...,<VSIDn>} {start | stop}
```

# Configuring the Cluster Member ID Mode in Local Logs

**Important** - In a Cluster, you must configure all the Cluster Members in the same way.

## Description

This command configures how to show the Cluster Member in the local ClusterXL logs - by its Member ID (default), or its Member Name.

This configuration applies to these local logs:

- /var/log/messages
- dmesg
- \$FWDIR/log/fwd.elg

See ["Viewing the Cluster Member ID Mode in Local Logs" on page 1420](#).

## Syntax

| Shell       | Command                                            |
|-------------|----------------------------------------------------|
| Gaia Clish  | <code>set cluster member idmode {id   name}</code> |
| Expert mode | <code>cphaconf mem_id_mode {id   name}</code>      |

## Example

```
[Expert@Member1:0]# cphaprob names
Current member print mode in local logs is set to: ID
[Expert@Member1:0]#
[Expert@Member1:0]# cphaconf mem_id_mode name
Member print mode in local logs: NAME
[Expert@Member1:0]#
[Expert@Member1:0]# cphaprob names
Current member print mode in local logs is set to: NAME
[Expert@Member1:0]#
```

# Registering a Critical Device

**Important** - In a Cluster, you must configure all the Cluster Members in the same way.

## Description

You can add a user-defined critical device to the default list of critical devices. Use this command to register <device> as a critical process, and add it to the list of devices that must run for the Cluster Member to be considered active. If <device> fails, then the Cluster Member is seen as failed.

If a Critical Device fails to report its state to the Cluster Member in the configured timeout, the Critical Device, and by design the Cluster Member, are seen as failed.

Define the status of the Critical Device that is reported to ClusterXL upon registration.

This initial status can be one of these:

- **ok** - Critical Device is alive.
- **init** - Critical Device is initializing. The Cluster Member is Down. In this state, the Cluster Member cannot become Active.
- **problem** - Critical Device failed. If this state is reported to ClusterXL, the Cluster Member immediately goes Down. This causes a failover.

## Syntax

| Shell          | Command                                                                                                                                          |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| Gaia<br>Clish  | N / A                                                                                                                                            |
| Expert<br>mode | <code>cphaconf set_pnote -d &lt;Name of Critical Device&gt; -t<br/>&lt;Timeout in Sec&gt; -s {ok   init   problem} [-p] [-g]<br/>register</code> |

### Notes:

- The "-t" flags specifies how frequently to expect the periodic reports from this Critical Device.  
If no periodic reports should be expected, then enter the value 0 (zero).
- The "-p" flag makes these changes permanent (survive reboot).
- The "-g" flag applies the command to all configured Virtual Systems.

## Restrictions

- Total number of critical devices (pnodes) on Cluster Member is limited to 16.
- Name of any critical device (pnode) on Cluster Member is limited to 15 characters, and must not include white spaces.

## Related topics

- [\*"Viewing Critical Devices" on page 1381\*](#)
- [\*"Reporting the State of a Critical Device" on page 1352\*](#)
- [\*"Registering Critical Devices Listed in a File" on page 1354\*](#)
- [\*"Unregistering a Critical Device" on page 1351\*](#)
- [\*"Unregistering All Critical Devices" on page 1356\*](#)

## Example use case

This example assumes that all other Critical Devices report their statuses as "ok".

Do these steps on each Cluster Member:

1. Create a shell script that does these actions:
  - a. Examine the used space in the critical disk partitions.
  - b. If the used space in these partitions:
    - Is above the threshold, then register a user-defined Critical Device and report its status as "problem".

As a result, the Cluster Member changes its cluster state to "Down" (if there is at least one Cluster Member in the status "Active").

  - Is below the threshold, then register a user-defined Critical Device and report its status as "ok".

As a result, the Cluster Member changes its cluster state to "Standby" or "Active".

Example script syntax:

```
#!/bin/bash

# Get the used % in the partition lv_current
var_lv_current=$(df -h | grep lv_current | awk '{print $5}' | sed 's/[%]//')
# Get the used % in the partition lv_log
var_lv_log=$(df -h | grep lv_log | awk '{print $5}' | sed 's/[%]//')

if [ "$var_lv_current" -gt 90 -o "$var_lv_log" -gt 90 ];
then
    # If the partition is full, then bring the cluster
member down
    $FWDIR/bin/cphaconf set_pnote -d Storage -s problem
report
else
    # If the partition is free enough, then bring the
cluster member up
    $FWDIR/bin/cphaconf set_pnote -d Storage -s ok report
    $FWDIR/bin/cphaconf set_pnote -d Storage unregister
fi
```

2. Configure a scheduled job to run this shell script at the relevant time intervals.

See the [\*R82.10 Gaia Administration Guide\*](#).

# Unregistering a Critical Device

**Important** - In a Cluster, you must configure all the Cluster Members in the same way.

## Description

This command unregisters a user-defined Critical Device (Pnote). This means that this device is no longer considered critical.

If a Critical Device was registered with a state "problem", before you ran this command, then after you run this command, the status of the Cluster Member depends only on the states of the remaining Critical Devices.

## Syntax

| Shell       | Command                                                                                     |
|-------------|---------------------------------------------------------------------------------------------|
| Gaia Clish  | N/A                                                                                         |
| Expert mode | <code>cphaconf set_pnote -d &lt;Name of Critical Device&gt; [-p] [-g]<br/>unregister</code> |

### Notes:

- The "-p" flag makes these changes permanent. This means that after you reboot, these Critical Devices remain unregistered.
- The "-g" flag applies the command to all configured Virtual Systems.

# Reporting the State of a Critical Device

**Important** - In a Cluster, you must configure all the Cluster Members in the same way.

## Description

This command manually reports (changes) the state of a Critical Device to ClusterXL.

The reported state can be one of these:

- **ok** - Critical Device is alive.
- **init** - Critical Device is initializing. The Cluster Member is Down. In this state, the Cluster Member cannot become Active.
- **problem** - Critical Device failed. If this state is reported to ClusterXL, the Cluster Member immediately goes Down. This causes a failover.

If a Critical Device fails to report its state to the Cluster Member within the defined timeout, the Critical Device, and by design the Cluster Member, are seen as failed. This is true only for Critical Devices with timeouts. If a Critical Device is registered with the "-t 0" parameter, there is no timeout. Until the Critical Device reports otherwise, the state of the Critical Device is considered to be the last reported state.

## Syntax

| Shell          | Command                                                                                                 |
|----------------|---------------------------------------------------------------------------------------------------------|
| Gaia<br>Clish  | N / A                                                                                                   |
| Expert<br>mode | <code>cphaconf set_pnote -d &lt;Name of Critical Device&gt; -s {ok   init   problem} [-g] report</code> |

### Notes:

- The "-g" flag applies the command to all configured Virtual Systems.
- If the "<Name of Critical Device>" reports its state as "problem", then the Cluster Member reports its state as failed.

## Registering Critical Devices Listed in a File

**Important** - In a Cluster, you must configure all the Cluster Members in the same way.

### Description

This command registers all the user-defined Critical Devices listed in the specified file.

This file must be a plain-text ASCII file, with each Critical Device defined on a separate line.

Each definition must contain three parameters, which must be separated by a space or a tab character:

```
<Name of Device> <Timeout> <Status>
```

Where:

| Parameter                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>&lt;Name of Device&gt;</i> | <p>The name of the Critical Device.</p> <ul style="list-style-type: none"> <li>Maximum name length is 15 characters</li> <li>The name must not include white spaces (space or tab characters).</li> </ul>                                                                                                                                                                                                                                                                                                                       |
| <i>&lt;Timeout&gt;</i>        | <p>If the Critical Device <i>&lt;Name of Device&gt;</i> fails to report its state to the Cluster Member within this specified number of seconds, the Critical Device (and by design the Cluster Member), are seen as failed.</p> <p>For no timeout, use the value 0 (zero).</p>                                                                                                                                                                                                                                                 |
| <i>&lt;Status&gt;</i>         | <p>The Critical Device <i>&lt;Name of Device&gt;</i> reports one of these statuses to the Cluster Member:</p> <ul style="list-style-type: none"> <li><code>ok</code> - Critical Device is alive.</li> <li><code>init</code> - Critical Device is initializing. The Cluster Member is Down. In this state, the Cluster Member cannot become Active.</li> <li><code>problem</code> - Critical Device failed. If this state is reported to ClusterXL, the Cluster Member immediately goes Down. This causes a failover.</li> </ul> |

## Syntax

| Shell       | Command                                                                               |
|-------------|---------------------------------------------------------------------------------------|
| Gaia Clish  | N / A                                                                                 |
| Expert mode | <pre>cphaconf set_pnote -f /&lt;Path&gt;/&lt;Name of File&gt; [-g]<br/>register</pre> |

**Note** - The "-g" flag applies the command to all configured Virtual Systems.

# Unregistering All Critical Devices

**Important** - In a Cluster, you must configure all the Cluster Members in the same way.

## Description

This command unregisters all critical devices from the Cluster Member.

## Syntax

| Shell       | Command                                            |
|-------------|----------------------------------------------------|
| Gaia Clish  | N / A                                              |
| Expert mode | <code>cphaconf set_pnote -a [-g] unregister</code> |

### Notes:

- The "-a" flag specifies that all Pnotes must be unregistered
- The "-g" flag applies the command to all configured Virtual Systems

# Configuring the Cluster Control Protocol (CCP) Settings

 **Important** - In a Cluster, you must configure all the Cluster Members in the same way.

## Description

Cluster Members configure the Cluster Control Protocol (CCP) mode automatically.

 **Important** - In R82.10, the CCP always runs in the unicast mode.

You can configure the Cluster Control Protocol (CCP) Encryption on the Cluster Members.

See ["Viewing the Cluster Control Protocol \(CCP\) Settings" on page 1427](#).

## Syntax for configuring the Cluster Control Protocol (CCP) Encryption

| Shell       | Command                                                                                                  |
|-------------|----------------------------------------------------------------------------------------------------------|
| Gaia Clish  | <code>set cluster member ccpenc {off   on}</code>                                                        |
| Expert mode | <code>cphaconf ccp_encrypt {off   on}</code><br><code>cphaconf ccp_encrypt_key &lt;Key String&gt;</code> |

# Initiating Manual Cluster Failover

## Description

This command initiates a manual cluster failover (see [sk55081](#)).

## Syntax

| Shell       | Command                                           |
|-------------|---------------------------------------------------|
| Gaia Clish  | <code>set cluster member admin {down   up}</code> |
| Expert mode | <code>clusterXL_admin {down   up}</code>          |

Example

```
[Expert@Member1:0]# cphaprob state
```

```

```

## Configuring the Minimum Number of Required Subordinate Interfaces for Bond Load Sharing

 **Important** - In a Cluster, you must configure all the Cluster Members in the same way.

### Description

ClusterXL considers a bond in Load Sharing mode to be in the "down" state when fewer than a minimum number of required subordinate interfaces stay in the "up" state.

By default, the minimum number of required subordinate interfaces, which must stay in the "up" state in a bond of **n** subordinate interfaces is **n-1**.

If one more subordinate interface fails (when **n-2** subordinate interfaces stay in the "up" state), ClusterXL considers the bond interface to be in the "down" state, even if the bond contains more than two subordinate interfaces.

If a smaller number of subordinate interfaces can pass the expected traffic, you can configure explicitly the minimum number of required subordinate interfaces.

Divide your maximum expected traffic speed by the speed of your subordinate interfaces and round up the result to find an applicable minimum number of required subordinate interfaces.

### Notes:

- Cluster Members save the configuration in the `$FWDIR/conf/cpha_bond_ls_config.conf` file.
- The commands below save the changes in this file.
- Each line in the file has this syntax:

```
<Name of Bond Interface> <Minimum Number of Required Subordinate Interfaces>
```

In addition, see ["Viewing Bond Interfaces" on page 1402](#).

### Syntax to add the minimum number of required subordinate interfaces for a specific Bond interface

| Shell         | Command                                                                                                                                      |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| Gaia<br>Clish | <code>set interface &lt;Name of Bond Interface&gt; links &lt;Minimum Number of Requirement Subordinate Interfaces between 1 and 8&gt;</code> |
| Expert mode   | <code>cphaconf bond_ls set &lt;Name of Bond Interface&gt; &lt;Minimum Number of Required Subordinate Interfaces between 1 and 8&gt;</code>   |

**Syntax to remove the configured minimum number of required subordinate interfaces for a specific Bond interface**

| Shell       | Command                                                             |
|-------------|---------------------------------------------------------------------|
| Gaia Clish  | <code>set interface &lt;Name of Bond Interface&gt; links 0</code>   |
| Expert mode | <code>cphaconf bond_ls remove &lt;Name of Bond Interface&gt;</code> |

**Syntax to see the current configuration of the minimum number of required subordinate interfaces**

| Shell       | Command                                                          |
|-------------|------------------------------------------------------------------|
| Gaia Clish  | <code>show interface &lt;Name of Bond Interface&gt; links</code> |
| Expert mode | <code>cat \$FWDIR/conf/cpha_bond_ls_config.conf</code>           |

**Procedure for Gaia Clish**

| Step | Instructions                                                                                                                                                                                                                    |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1    | Connect to the command line on each Cluster Member.                                                                                                                                                                             |
| 2    | Log in to Gaia Clish.                                                                                                                                                                                                           |
| 3    | Add or remove the minimum number of required subordinate interfaces for a specific Bond interface:<br><pre>set interface &lt;Name of Bond Interface&gt; links {Minimum Number of Requirement Subordinate Interfaces}   0}</pre> |
| 4    | Save the configuration:<br><pre>save config</pre>                                                                                                                                                                               |
| 5    | Examine the configuration:<br><pre>show interface &lt;Name of Bond Interface&gt; links</pre>                                                                                                                                    |
| 6    | In SmartConsole, install the Access Control policy on this cluster object.                                                                                                                                                      |

**Procedure for the Expert mode**

| Step | Instructions                                                                                                                                                                                                                                                  |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1    | Connect to the command line on each Cluster Member.                                                                                                                                                                                                           |
| 2    | Log in to the Expert mode.                                                                                                                                                                                                                                    |
| 3    | Add or remove the minimum number of required subordinate interfaces for a specific Bond interface: <div> <pre>cphaconf bond_ls set &lt;Bond&gt; &lt;Minimum Number of Subordinate Interfaces&gt;</pre> <pre>cphaconf bond_ls remove &lt;Bond&gt;</pre> </div> |
| 4    | Examine the configuration: <div> <pre>cat \$FWDIR/conf/cpha_bond_ls_config.conf</pre> </div>                                                                                                                                                                  |
| 5    | In SmartConsole, install the Access Control policy on this cluster object.                                                                                                                                                                                    |

**Example for the Expert mode**

```
[Expert@Member1:0]# cat $FWDIR/conf/cpha_bond_ls_config.conf
# ... (truncated for brevity) ...
# Example:
# bond0 2

[Expert@Member1:0]#

[Expert@Member1:0]# cphaconf bond_ls set bond1 2
Set operation succeeded

[Expert@Member1:0]# cat $FWDIR/conf/cpha_bond_ls_config.conf
# ... (truncated for brevity) ...
# Example:
# bond0 2

bond1 2
[Expert@Member1:0]#

[Expert@Member1:0]# cphaconf bond_ls remove bond1
Remove operation succeeded

[Expert@Member1:0]#

[Expert@Member1:0]# cat $FWDIR/conf/cpha_bond_ls_config.conf
# ... (truncated for brevity) ...
# Example:
# bond0 2

[Expert@Member1:0]#
```

## Configuring Link Monitoring on the Cluster Interfaces

**Important** - In a Cluster, you must configure all the Cluster Members in the same way.

### Description

This procedure configures the Cluster Member to monitor only the physical link on the cluster interfaces (instead of monitoring the Cluster Control Protocol (CCP) packets):

- If a link disappears on the configured interface, the Cluster Member changes the interface's state to **DOWN**.

This causes the Cluster Member to change its state to **DOWN**.

- If a link appears again on the configured interface, the Cluster Member changes the interface's state back to **UP**.

This causes the Cluster Member to change its state back to **ACTIVE** or **STANDBY**.

See ["Viewing Cluster State" on page 1375](#).

## Procedure

| Step | Instructions                                                                                                                                                                                                                                                                                                                          |

# Configuring the Multi-Version Cluster Mechanism

## Description

This command changes the state of the Multi-Version Cluster (MVC) Mechanism - enable or disable it.

### Important:

- The MVC Mechanism is *disabled* by default.
- For limitations of the MVC Mechanism, see the [R82.10 Installation and Upgrade Guide](#) > Chapter *Upgrading Gateways and Clusters* > Section *Upgrading ClusterXL, VSX Cluster, VRRP Cluster* > Section *Multi-Version Cluster Upgrade*.

## Syntax

| Shell       | Command                                        |
|-------------|------------------------------------------------|
| Gaia Clish  | <code>set cluster member mvc {off   on}</code> |
| Expert mode | <code>cphaconf mvc {off   on}</code>           |

## Parameters

| Parameter        | Description                                        |
|------------------|----------------------------------------------------|
| <code>off</code> | Disables the MVC Mechanism on this Cluster Member. |
| <code>on</code>  | Enables the MVC Mechanism on this Cluster Member.  |

### Notes:

- This command does *not* provide an output. To view the current state of the MVC Mechanism, see ["Viewing the State of the Multi-Version Cluster Mechanism" on page 1428](#).
- The change made with this command survives reboot.
- If a specific scenario requires you to disable the MVC Mechanism before the first start of an R82.10 Cluster Member (for example, immediately after an upgrade to R82.10), then disable it before the first policy installation on this Cluster Member.

# Configuring Duration of Forced Failover in High Availability Mode

## Description

In the ClusterXL High Availability mode, you can force the current Active cluster member to fail over to the specified cluster member for the specified number of minutes.

After the specified duration ends, or after you manually disable the forced failover, the cluster recovers based on the mode you configured in the cluster object:

- **Primary Up** - The cluster fails over to the cluster member that is configured as primary (if it is not currently Active).
- **Active Up** - The current Active cluster member remains Active.

## Syntax

| Shell       | Command                                                                                      |
|-------------|----------------------------------------------------------------------------------------------|
| Gaia Clish  | <code>set cluster force_failover member_id &lt;ID&gt; {time &lt;Minutes&gt; on   off}</code> |
| Expert mode | <code>cphaconf force_failover member_id &lt;ID&gt; {time &lt;Minutes&gt; on   off}</code>    |

## Parameters

| Parameter | Description                                                                                                                                                      |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ID>      | Specifies the ID of the cluster member, to which the current Active cluster member must fail over.<br>See <a href="#">"Viewing Cluster State" on page 1375</a> . |
| off       | Disables the forced failover.                                                                                                                                    |
| on        | Enables the forced failover.                                                                                                                                     |

# ClusterXL Monitoring Commands

## Description

Use the monitoring commands to make sure that the cluster and the Cluster Members work properly, and to define Critical Devices. A Critical Device (also known as a *Problem Notification*, or *pnote*) is a special software device on each Cluster Member, through which the critical aspects for cluster operation are monitored. When the critical monitored component on a Cluster Member fails to report its state on time, or when its state is reported as problematic, the state of that member is immediately changed to 'Down'.

## Syntax

### Notes:

- In Gaia Clish:  
Enter the `show cluster<ESC><ESC>` to see all the available commands.
- In Expert mode:  
Run the `cphaprob` command see all the available commands.  
You can run the `cphaprob` commands from Gaia Clish as well.
- Syntax legend:
  1. Curly brackets or braces { }:  
Enclose a list of available commands or parameters, separated by the vertical bar |, from which user can enter only one.
  2. Angle brackets < >:  
Enclose a variable - a supported value user needs to specify explicitly.
  3. Square brackets or brackets [ ]:  
Enclose an optional command or parameter, which user can also enter.
- You can include these commands in scripts to run them automatically.  
The meaning of each command is explained in the next sections.

Table: ClusterXL Monitoring Commands

| Description of Command                                                                                                               | Command in Gaia Clish                                    | Command in Expert Mode                         |
|--------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|------------------------------------------------|
| Show states of Cluster Members and their names (see <a href="#">"Viewing Cluster State" on page 1375</a> )                           | <code>show cluster state</code>                          | <code>cphaprob [-vs &lt;VSID&gt;] state</code> |
| Show Critical Devices (Pnotes) and their states on the Cluster Member (see <a href="#">"Viewing Critical Devices" on page 1381</a> ) | <code>show cluster members pnotes {all   problem}</code> | <code>cphaprob [-l] [-ia] [-e] list</code>     |

Table: ClusterXL Monitoring Commands (continued)

| Description of Command                                                                                                                                                                                                                | Command in Gaia Clish                                             | Command in Expert Mode                                 |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------|--------------------------------------------------------|
| Show cluster interfaces on the cluster member (see <a href="#">"Viewing Cluster Interfaces" on page 1393</a> )                                                                                                                        | show cluster members interfaces {all   secured   virtual   vlans} | cphaprob [-vs all] [-a] [-m] if                        |
| Show cluster bond configuration on the Cluster Member (see <a href="#">"Viewing Bond Interfaces" on page 1402</a> )                                                                                                                   | show cluster bond {all   name <bond_name>}                        | cphaprob show_bond [<bond_name>]                       |
| Show groups of bonds on the Cluster Member (see <a href="#">"Viewing Bond Interfaces" on page 1402</a> )                                                                                                                              | N / A                                                             | cphaprob show_bond_groups                              |
| Show (and reset) cluster failover statistics on the Cluster Member (see <a href="#">"Viewing Cluster Failover Statistics" on page 1407</a> )                                                                                          | show cluster failover [reset {count   history}]                   | cphaprob [-reset {-c   -h}] [-l <count>] show_failover |
| Show information about the software version (including hotfixes) on the local Cluster Member and its matches/mismatches with other Cluster Members (see <a href="#">"Viewing Software Versions on Cluster Members" on page 1409</a> ) | show cluster release                                              | cphaprob release                                       |
| Show Delta Sync statistics on the Cluster Member (see <a href="#">"Viewing Delta Synchronization" on page 1410</a> )                                                                                                                  | show cluster statistics sync [reset]                              | cphaprob [-reset] syncstat                             |
| Show Delta Sync statistics for the Connections table on the Cluster Member (see <a href="#">"Viewing Cluster Delta Sync Statistics for Connections Table" on page 1418</a> )                                                          | show cluster statistics transport [reset]                         | cphaprob [-reset] ldstat                               |
| Show the Cluster Control Protocol (CCP) mode on the Cluster Member (see <a href="#">"Viewing Cluster Interfaces" on page 1393</a> )                                                                                                   | show cluster members interfaces virtual                           | cphaprob [-vs all] -a if                               |

```

## List of the Expert mode "cphaprob" commands

**Note** - Some commands are not applicable to 3rd-party clusters.

```
cphaprob [-vs <VSID>] state
cphaprob [-reset {-c | -h}] [-l <count>] show_failover
cphaprob names
cphaprob [-reset] [-a] syncstat
cphaprob [-reset] ldstat
cphaprob [-l] [-i[a]] [-e] list
cphaprob [-vs all] [-a] [-m] if
cphaprob show_bond [<bond_name>]
cphaprob show_bond_groups
cphaprob igmp
cphaprob fcustat
cphaprob [-m] tablestat
cphaprob routedifcs
cphaprob roles
cphaprob release
cphaprob mvc
cphaprob ccp_encrypt
cphaprob [{-d | -f | -s}] corr
cphaprob show_vsels_groups
```

# Viewing Cluster State

## Description

This command monitors the cluster status (after you set up the cluster).

## Syntax

| Shell       | Command                                                                                                             |
|-------------|---------------------------------------------------------------------------------------------------------------------|
| Gaia Clish  | <ol style="list-style-type: none"> <li>1. set virtual-system &lt;VSID&gt;</li> <li>2. show cluster state</li> </ol> |
| Expert mode | cphaprob [-vs <VSID>] state                                                                                         |

## Example

```
Member1> show cluster state

Cluster Mode:   High Availability (Active Up) with IGMP Membership

ID             Unique Address  Assigned Load  State           Name
-----
1 (local)      11.22.33.245     100%           ACTIVE(!)       Member1
2              11.22.33.246     0%             DOWN            Member2

Active PNOTES: COREXL

Last member state change event:
  Event Code:           CLUS-116505
  State change:         INIT -> ACTIVE(!)
  Reason for state change: All other machines are dead (timeout), FULLSYNC PNOTE
  Event time:           Sun Sep  8 15:28:39 2019
v Cluster failover count:
  Failover counter:      0
  Time of counter reset: Sun Sep  8 15:28:21 2019 (reboot)

Member1>
```

Description of the "cphaprob state" command output fields:

Table: Description of the output fields

| Field          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| State          | <ul style="list-style-type: none"> <li>▪ In the ClusterXL High Availability mode, only one Cluster Member in a fully-functioning cluster must be <i>ACTIVE</i>, and the other Cluster Members must be in the <i>STANDBY</i> state.</li> <li>▪ In the ClusterXL Load Sharing modes (Unicast and Multicast), all Cluster Members in a fully-functioning cluster must be <i>ACTIVE</i>.</li> <li>▪ In 3rd-party clustering configuration, all Cluster Members in a fully-functioning cluster must be <i>ACTIVE</i>. This is because this command only reports the status of the Full Synchronization process.</li> </ul> <p>See the summary table below.</p> |
| Name           | Shows the names of Cluster Members' objects as configured in SmartConsole.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Active PNOTEs  | Shows the Critical Devices that report their states as "problem" (see <a href="#">"Viewing Critical Devices" on page 1381</a> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

Table: Description of the output fields (continued)

| Field                                 | Description                                                                                                                                                                                                      |
|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Last member state change event</b> | Shows information about the last time this Cluster Member changed its cluster state.                                                                                                                             |
| <b>Event Code</b>                     | Shows an event code.<br>For information, see <a href="#">sk125152</a> .                                                                                                                                          |
| <b>State change</b>                   | Shows the previous cluster state and the new cluster state of this Cluster Member.                                                                                                                               |
| <b>Reason for state change</b>        | Shows the reason why this Cluster Member changed its cluster state.                                                                                                                                              |
| <b>Event time</b>                     | Shows the date and the time when this Cluster Member changed its cluster state.                                                                                                                                  |
| <b>Last cluster failover event</b>    | Shows information about the last time a cluster failover occurred.                                                                                                                                               |
| <b>Transition to new ACTIVE</b>       | Shows which Cluster Member became the new <i>Active</i> .                                                                                                                                                        |
| <b>Reason</b>                         | Shows the reason for the last cluster failover.                                                                                                                                                                  |
| <b>Event time</b>                     | Shows the date and the time of the last cluster failover.                                                                                                                                                        |
| <b>Cluster failover count</b>         | Shows information about the cluster failovers.                                                                                                                                                                   |
| <b>Failover counter</b>               | Shows the number of cluster failovers since the boot.<br>Notes: <ul style="list-style-type: none"> <li>■ This value survives reboot.</li> <li>■ This counter is synchronized between Cluster Members.</li> </ul> |
| <b>Time of counter reset</b>          | Shows the date and the time of the last counter reset, and the reset initiator.                                                                                                                                  |

When you examine the state of the Cluster Member, consider whether it forwards packets, and whether it has a problem that prevents it from forwarding packets. Each state reflects the result of a test on critical devices. This table shows the possible cluster states, and whether or not they represent a problem.

Table: Description of the cluster states

| Cluster State                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Forwarding packets? | Is this state a problem? |
|------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|--------------------------|
| ACTIVE                                               | Everything is OK.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Yes                 | No                       |
| ACTIVE(!)<br>ACTIVE(!F)<br>ACTIVE(IP)<br>ACTIVE(!FP) | <p>A problem was detected, but the Cluster Member still forwards packets, because it is the only member in the cluster, or because there are no other Active members in the cluster. In any other situation, the state of the member is <i>Down</i>.</p> <ul style="list-style-type: none"> <li>■ ACTIVE (!) - See above.</li> <li>■ ACTIVE (!F) - See above. Cluster Member is in the freeze state.</li> <li>■ ACTIVE (!P) - See above. This is the Pivot Cluster Member in Load Sharing Unicast mode.</li> <li>■ ACTIVE (!FP) - See above. This is the Pivot Cluster Member in Load Sharing Unicast mode and it is in the freeze state.</li> </ul> | Yes                 | Yes                      |
| DOWN                                                 | One of the Critical Devices reports its state as "problem" (see <a href="#">"Viewing Critical Devices" on page 1381</a> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | No                  | Yes                      |
| LOST                                                 | The peer Cluster Member lost connectivity to this local Cluster Member (for example, while the peer Cluster Member is rebooted).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | No                  | Yes                      |

Table: Description of the cluster states (continued)

| Cluster State | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Forwarding packets? | Is this state a problem? |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|--------------------------|
| READY         | <p>State <i>Ready</i> means that the Cluster Member recognizes itself as a part of the cluster and is literally ready to go into action, but, by design, something prevents it from taking action. Possible reasons that the Cluster Member is not yet Active include:</p> <ul style="list-style-type: none"> <li>■ Not all required software components were loaded and initialized yet and/or not all configuration steps finished successfully yet. Before a Cluster Member becomes <i>Active</i>, it sends a message to the rest of the Cluster Members, to check if it can become <i>Active</i>. In High Availability mode it checks if there is already an Active member and in Load Sharing Unicast mode it checks if there is a Pivot member already. The member remains in the <i>Ready</i> state until it receives the response from the rest of the Cluster Members and decides which, which state to choose next (<i>Active</i>, <i>Standby</i>, <i>Pivot</i>, or <i>non-Pivot</i>).</li> <li>■ Software installed on this Cluster Member has a higher version than all the other Cluster Members. For example, when a cluster is upgraded from one version of Check Point Security Gateway to another, and the Cluster Members have different versions of Check Point Security Gateway, the Cluster Members with the new version have the <i>Ready</i> state, and the Cluster Members with the previous version have the <i>Active/Active Attention</i> state.</li> </ul> | No                  | No                       |

Table: Description of the cluster states (continued)

| Cluster State  | Description                                                                                                                                                                                                            | Forwarding packets? | Is this state a problem? |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|--------------------------|
|                | <p>This applies only when the Multi-Version Cluster Mechanism is disabled (see <i>"Viewing the State of the Multi-Version Cluster Mechanism" on page 1428</i>).</p> <p>See <a href="#">sk42096</a> for a solution.</p> |                     |                          |
| <b>STANDBY</b> | Applies only to a High Availability mode. Means that the Cluster Member waits for an Active Cluster Member to fail in order to start packet forwarding.                                                                | No                  | No                       |
| <b>BACKUP</b>  | Applies only to a VSX Cluster in Virtual System Load Sharing mode with three or more Cluster Members configured. State of a Virtual System on a third (and so on) VSX Cluster Member.                                  | No                  | No                       |
| <b>INIT</b>    | The Cluster Member is in the phase after the boot and until the Full Sync completes.                                                                                                                                   | No                  | No                       |

# Viewing Critical Devices

## Description

There are a number of built-in Critical Devices, and the Administrator can define additional Critical Devices.

When a Critical Device reports its state as a "problem", the Cluster Member reports its state as "DOWN".

To see the list of Critical Devices on a Cluster Member, and of all the other Cluster Members, run the commands listed below on the Cluster Member.

Table: Built-in Critical Devices

| Critical Device        | Description                                                                         | Meaning of the "OK" state                                                                                           | Meaning of the "problem" state                                                                                            |
|------------------------|-------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------|
| Problem Notification   | Monitors all the Critical Devices.                                                  | None of the Critical Devices on this Cluster Member report its state as problem.                                    | At least one of the Critical Devices on this Cluster Member reports its state as "problem".                               |
| Init                   | Monitors if "HA module" was initialized successfully. See <a href="#">sk36372</a> . | This Cluster Member receives cluster state information from peer Cluster Members.                                   |                                                                                                                           |
| Interface Active Check | Monitors the state of cluster interfaces.                                           | All cluster interfaces on this Cluster Member are up (CCP packets are sent and received on all cluster interfaces). | At least one of the cluster interfaces on this Cluster Member is down (CCP packets are not sent and/or received on time). |

Table: Built-in Critical Devices (continued)

| Critical Device              | Description                                                               | Meaning of the "OK" state                                                                                         | Meaning of the "problem" state                                                                                                                                                                                                     |
|------------------------------|---------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Load Balancing Configuration | Currently is not used (see <a href="#">sk36373</a> ).                     |                                                                                                                   |                                                                                                                                                                                                                                    |
| Recovery Delay               | Monitors the state of a Virtual System (see <a href="#">sk92353</a> ).    | State of a Virtual System can be changed on this Cluster Member.                                                  | State of a Virtual System cannot be changed yet on this Cluster Member.                                                                                                                                                            |
| CoreXL Configuration         | Monitors CoreXL configuration for inconsistencies on all Cluster Members. | Number of configured CoreXL Firewall instances on this Cluster Member is the same as on all peer Cluster Members. | Number of configured CoreXL Firewall instances on this Cluster Member is different from peer Cluster Members.<br><b>Important</b> - A Cluster Member with a greater number of CoreXL Firewall instances changes its state to DOWN. |
| Fullsync                     | Monitors if Full Sync on this Cluster Member completed successfully.      | This Cluster Member completed Full Sync successfully.                                                             | This Cluster Member was not able to complete Full Sync.                                                                                                                                                                            |
| Policy                       | Monitors if the Security Policy is installed.                             | This Cluster Member successfully installed Security Policy.                                                       | Security Policy is not currently installed on this Cluster Member.                                                                                                                                                                 |

Table: Built-in Critical Devices (continued)

| Critical Device | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Meaning of the "OK" state                                                        | Meaning of the "problem" state                                                         |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| fwd             | Monitors the Security Gateway process called <code>fwd</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | <code>fwd</code> daemon on this Cluster Member reported its state on time.       | <code>fwd</code> daemon on this Cluster Member did not report its state on time.       |
| cphad           | Monitors the ClusterXL process called <code>cphamcset</code> . also see the <code>\$FWDIR/log/cphamcset.elg</code> file.                                                                                                                                                                                                                                                                                                                                                                                                             | <code>cphamcset</code> daemon on this Cluster Member reported its state on time. | <code>cphamcset</code> daemon on this Cluster Member did not report its state on time. |
| routed          | Monitors the Gaia process called <code>routed</code> .<br> <b>Note</b> - On Scalable Platform Security Groups, prevents traffic outage by allowing the <code>routed</code> daemon to synchronize BGP routes. In BGP DR Manager failback scenarios, the old BGP DR manager will go down for 2 minutes. When the <code>routed</code> daemon restarts on the BGP DR Manager, the BGP DR Manager will go down for 2 minutes. (Limitation ID 01862808.) | <code>routed</code> daemon on this Cluster Member reported its state on time.    | <code>routed</code> daemon on this Cluster Member did not report its state on time.    |
| cvpnd           | Monitors the Mobile Access back-end process called <code>cvpnd</code> . This pnote appears if Mobile Access Software Blade is enabled.                                                                                                                                                                                                                                                                                                                                                                                               | <code>cvpnd</code> daemon on this Cluster Member reported its state on time.     | <code>cvpnd</code> daemon on this Cluster Member did not report its state on time.     |

Table: Built-in Critical Devices (continued)

| Critical Device | Description                                                   | Meaning of the "OK" state                                                                                                                                       | Meaning of the "problem" state                                                                                                                       |
|-----------------|---------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| ted             | Monitors the Threat Emulation process called ted.             | ted daemon on this Cluster Member reported its state on time.                                                                                                   | ted daemon on this Cluster Member did not report its state on time.                                                                                  |
| VSX             | Monitors all Virtual Systems in VSX Cluster.                  | On VS0, means that states of all Virtual Systems are not Down on this Cluster Member. On other Virtual Systems, means that VS0 is alive on this Cluster Member. | Minimum of blocking states of all Virtual Systems is not "active" (the VSIDs will be printed on the line Problematic VSIDs:) on this Cluster Member. |
| VSX Config      | Monitors the consistency and health of the VSX configuration. | All Virtual Systems (VS) and Virtual Routers are properly configured and synchronized.                                                                          | There is a mismatch or inconsistency in the VSX configuration between cluster members.                                                               |

Table: Built-in Critical Devices (continued)

| Critical Device | Description                                                                                                                                                                                 | Meaning of the "OK" state                                                                                                                                                    | Meaning of the "problem" state                                                                                                                                                                                                       |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Instances       | This Critical Device appears in VSX HA mode (not VSLS) cluster.                                                                                                                             | The number of CoreXL Firewall instances in the received CCP packet matches the number of loaded CoreXL Firewall instances on this VSX Cluster Member or this Virtual System. | There is a mismatch between the number of CoreXL Firewall instances in the received CCP packet and the number of loaded CoreXL Firewall instances on this VSX Cluster Member or this Virtual System (see <a href="#">sk106912</a> ). |
| Hibernating     | This pnote appears in VSX VSLS mode cluster with 3 and more Cluster Members. This pnote shows if this Virtual System is in "Backup" (hibernated) state. Also see <a href="#">sk114557</a> . | This Virtual System is in "Backup" (hibernated) state on this Cluster Member.                                                                                                |                                                                                                                                                                                                                                      |
| admin_down      | Monitors the Critical Device "admin_down".                                                                                                                                                  |                                                                                                                                                                              | User ran the <code>clusterXL_admin down</code> command on this Cluster Member. See <i>"The clusterXL_admin Script" on page 1442</i> .                                                                                                |
| host_monitor    | Monitors the Critical Device "host_monitor".<br>User executed the <code>\$FWDIR/bin/clusterXL_monitor_ips</code> script. See <i>"The clusterXL_monitor_ips Script" on page 1446</i> .       | All monitored IP addresses on this Cluster Member replied to pings.                                                                                                          | At least one of the monitored IP addresses on this Cluster Member did not reply to at least one ping.                                                                                                                                |

Table: Built-in Critical Devices (continued)

| Critical Device                                                 | Description                                                                                                                                        | Meaning of the "OK" state                                              | Meaning of the "problem" state                                                            |
|-----------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------|-------------------------------------------------------------------------------------------|
| A name of a user space process (except fwd, routed, cvpnd, ted) | Administrator executed the \$FWDIR/bin/clusterXL_monitor_process script. See <a href="#">"The clusterXL_monitor_process Script" on page 1450</a> . | All monitored user space processes on this Cluster Member are running. | At least one of the monitored user space on this Cluster Member processes is not running. |

Table: Built-in Critical Devices (continued)

| Critical Device | Description                                                                                                                    | Meaning of the "OK" state                           | Meaning of the "problem" state                                                                                                                                                                         |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Local Probing   | Monitors the probing mechanism on the cluster interfaces (see the term <b>Probing</b> in the <i>"Glossary" on page 2151</i> ). | CCP packets are received on all cluster interfaces. | At least one of the cluster interfaces on this Cluster Member does not (or did not) <b>receive</b> CCP packets for 5 seconds. The probing started for the network connected to the affected interface. |

Table: Built-in Critical Devices (continued)

| Critical Device | Description | Meaning of the "OK" state | Meaning of the "problem" state |
|-----------------|-------------|---------------------------|--------------------------------|
|                 |             |                           |                                |

**Syntax**

## Examples

### Example 1 - Critical Device 'fwd'

Critical Device `fwd` reports its state as `problem` because the `fwd` process is down.

```
[Expert@Member1:0]# cphaprob -l list

Built-in Devices:

Device Name: Interface Active Check
Current state: OK

Device Name: Recovery Delay
Current state: OK

Device Name: CoreXL Configuration
Current state: OK

Registered Devices:

Device Name: Fullsync
Registration number: 0
Timeout: none
Current state: OK
Time since last report: 1753.7 sec

Device Name: Policy
Registration number: 1
Timeout: none
Current state: OK
Time since last report: 1753.7 sec

Device Name: routed
Registration number: 2
Timeout: none
Current state: OK
Time since last report: 940.3 sec

Device Name: fwd
Registration number: 3
Timeout: 30 sec
Current state: problem
Time since last report: 1782.9 sec
Process Status: DOWN

Device Name: cphad
Registration number: 4
Timeout: 30 sec
Current state: OK
Time since last report: 1778.3 sec
Process Status: UP

Device Name: VSX
Registration number: 5
Timeout: none
Current state: OK
Time since last report: 1773.3 sec

Device Name: Init
Registration number: 6
Timeout: none
Current state: OK
Time since last report: 1773.3 sec

[Expert@Member1:0]#
```

**Example 2 - Critical Device 'CoreXL Configuration'**

Critical Device CoreXL Configuration reports its state as **problem** because the numbers of CoreXL Firewall instances do not match between the Cluster Members.

```
[Expert@Member1:0]# cphaprob -l list

Built-in Devices:

Device Name: Interface Active Check
Current state: OK

Device Name: Recovery Delay
Current state: OK

Device Name: CoreXL Configuration
Current state: problem (non-blocking)

Registered Devices:

Device Name: Fullsync
Registration number: 0
Timeout: none
Current state: OK
Time since last report: 1753.7 sec

Device Name: Policy
Registration number: 1
Timeout: none
Current state: OK
Time since last report: 1753.7 sec

Device Name: routed
Registration number: 2
Timeout: none
Current state: OK
Time since last report: 940.3 sec

Device Name: fwd
Registration number: 3
Timeout: 30 sec
Current state: OK
Time since last report: 1782.9 sec
Process Status: UP

Device Name: cphad
Registration number: 4
Timeout: 30 sec
Current state: OK
Time since last report: 1778.3 sec
Process Status: UP

Device Name: VSX
Registration number: 5
Timeout: none
Current state: OK
Time since last report: 1773.3 sec

Device Name: Init
Registration number: 6
Timeout: none
Current state: OK
Time since last report: 1773.3 sec

# Viewing Cluster Interfaces

## Description

This command shows the state of the Cluster Member interfaces and the virtual cluster interfaces.

ClusterXL treats the interfaces as Critical Devices. ClusterXL makes sure that interfaces can send and receive CCP packets.

ClusterXL also sets the required minimum number of functional interfaces to the largest number of functional interfaces ClusterXL detected since the last reboot. If the number of functional interfaces is less than the required number, ClusterXL declares the Cluster Member as failed and starts a failover. The same applies to the synchronization interfaces, where only good synchronization interfaces are counted.

When an interface is DOWN, it means that the interface cannot receive or send CCP packets, or both. An interface may also be able to receive, but not send CCP packets. The time you see in the command's output is the number of seconds that elapsed since the interface was last able to receive or send a CCP packet.

## Network Objective

In the Cluster object in the Management Server database, you assign the Network Objective to each interface.

This Network Objective determines a network type (network role) for the interface:

| Network Objective             | Description                                                                                                                                                                                                                                                                                    |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Cluster Interface</b>      | Configures a cluster interface that connects to an internal or external network.<br>Cluster Members monitor this interface.<br>A Cluster Member fails over to its peers if the cluster state of this interface changes to "DOWN".                                                              |
| <b>Cluster Sync Interface</b> | Configures a cluster Synchronization interface.<br>Cluster Members monitor this interface.<br>A Cluster Member fails over to its peers if the cluster state of this interface changes to "DOWN".                                                                                               |
| <b>Private</b>                | Configures an interface that is <b>not</b> part of the cluster.<br>Cluster Members do <b>not</b> monitor this interface.<br>A Cluster Member does <b>not</b> fail over to its peers if a fault occurs on this interface.<br>This option is recommended for the dedicated management interface. |

For more details, see the [ClusterXL Administration Guide](#).

## Syntax

| Shell       | Command                                                                                                                                                                                      |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Gaia Clish  | <ol style="list-style-type: none"> <li>1. <code>set virtual-system &lt;VSID&gt;</code></li> <li>2. <code>show cluster members interfaces {all   secured   virtual   vlans}</code></li> </ol> |
| Expert mode | <code>cphaprob [-vs all] [-a] [-m] if [&lt;Name of Interface&gt;]</code>                                                                                                                     |

Where:

| Command                                                  | Description                                                                                                                                                                                                                                                                                                                                                                          |

## Output

The output of these commands must be identical to the configuration in the cluster object's **Network Management** page in SmartConsole.

**Example 1: cphaprob -a -m if**

```
[Expert@Member1:0]# cphaprob -a -m if

CCP mode: Manual (Unicast)
Required interfaces: 4
Required secured interfaces: 1

Interface Name:      Status:

eth0                  UP
eth1 (S)              UP
eth2 (LM)             UP
bond1 (LS)            UP

S - sync, LM - link monitor, HA/LS - bond type

Virtual cluster interfaces: 3

eth0                  192.168.3.247
eth2                  44.55.66.247
bond1                 77.88.99.247

No VLANs are monitored on the member

[Expert@Member1:0]#
```

Description of the "cphaprob -a -m if" command output fields:

| Field, or Text                     | Description                                                                                                                                                                                                                           |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CCP mode</b>                    | Shows the CCP mode - "Unicast" (default), "Broadcast", or "Multicast".                                                                                                                                                                |
| <b>Required interfaces</b>         | Shows the total number of monitored cluster interfaces, including the Sync interface.<br>This number is based on the configuration of the cluster object > <b>Network Management</b> page.                                            |
| <b>Required secured interfaces</b> | Shows the total number of the required Sync interfaces.<br>This number is based on the configuration of the cluster object > <b>Network Management</b> page.                                                                          |
| <b>Non-Monitored</b>               | This means that Cluster Member does not monitor the state of this interface.<br>In SmartConsole, in the cluster object > <b>Network Management</b> page, administrator configured the Network Type <b>Private</b> for this interface. |

| Field, or Text                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| UP                                   | <p>This means that Cluster Member monitors the state of this interface.</p> <p>The current cluster state of this interface is UP, which means this interface can send and receive CCP packets.</p> <p>In SmartConsole, in the cluster object &gt; <b>Network Management</b> page, administrator configured one of these Network Types for this interface: <b>Cluster</b>, <b>Sync</b>, or <b>Cluster + Sync</b>.</p>                         |
| DOWN                                 | <p>This means that Cluster Members monitors the state of this interface.</p> <p>The current cluster state of this interface is DOWN, which means this interface cannot send CCP packets, receive CCP packets, or both.</p> <p>In SmartConsole, in the cluster object &gt; <b>Network Management</b> page, administrator configured one of these Network Types for this interface: <b>Cluster</b>, <b>Sync</b>, or <b>Cluster + Sync</b>.</p> |
| (S)                                  | <p>This interface is a Sync interface.</p> <p>In SmartConsole, in the cluster object &gt; <b>Network Management</b> page, administrator configured one of these Network Types for this interface: <b>Sync</b>, or <b>Cluster + Sync</b>.</p>                                                                                                                                                                                                 |
| (LM)                                 | <p>This interface is configured in the <code>\$FWDIR/conf/cpha_link_monitoring.conf</code> file.</p> <p>Cluster Member monitors only the link on this interface (does <b>not</b> monitor the received or sent CCP packets).</p> <p>See <a href="#">"Configuring Link Monitoring on the Cluster Interfaces" on page 1365</a>.</p>                                                                                                             |
| (HA)                                 | This interface is a Bond interface in High Availability mode.                                                                                                                                                                                                                                                                                                                                                                                |
| (LS)                                 | This interface is a Bond interface in Load Sharing mode.                                                                                                                                                                                                                                                                                                                                                                                     |
| Virtual cluster interfaces           | <p>Shows the total number of the configured virtual cluster interfaces.</p> <p>This number is based on the configuration of the cluster object &gt; <b>Network Management</b> page.</p>                                                                                                                                                                                                                                                      |
| No VLANs are monitored on the member | Shows the VLAN monitoring mode - there are no VLAN interfaces configured on the cluster interfaces.                                                                                                                                                                                                                                                                                                                                          |

| Field, or Text                                                                      | Description                                                                                                                                               |
|-------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Monitoring mode is Monitor all VLANs: All VLANs are monitored</b>                | Shows the VLAN monitoring mode - there are some VLAN interfaces configured on the cluster interfaces, and Cluster Member monitors all VLAN IDs.           |
| <b>Monitoring mode is Monitor specific VLAN: Only specified VLANs are monitored</b> | Shows the VLAN monitoring mode - there are some VLAN interfaces configured on the cluster interfaces, and Cluster Member monitors only specific VLAN IDs. |

### Example 2: cphaprob -a if eth1 (for a monitored cluster interface)

```
[Expert@Member1:0]# cphaprob -a if eth1
```

```
Interface name:      eth1
FW ifn:             2
IPv4 Address:       192.168.10.21/24
VIP:                192.168.10.20/24
MAC Address:        00:50:56:91:E1:2B
Link status:        Connected
Cluster interface status: UP
CCP mode:           Unicast
```

```
---- Unique IP's Table ----
```

| Member | IP-Address | MAC-Address |
|--------|------------|-------------|
|--------|------------|-------------|

|   |               |                   |
|---|---------------|-------------------|
| 1 | 192.168.10.22 | 00:50:56:91:AA:BB |
|---|---------------|-------------------|

```
Flags:
```

```
Link Monitored:      YES
```

```
Used:                YES
```

```
Sync:                NO
```

```
In Topology:         YES
```

```
[Expert@Member1:0]#
```

Example 3: cphaprob -a if eth3 (for a non-monitored cluster interface)

```
[Expert@Member1:0]# cphaprob -a if eth3

Interface name:          eth3
FW ifn:                  4
IPv4 Address:            10.20.30.40/24
VIP:                     No Virtual IP for this interface.
MAC Address:             00:50:56:91:E1:2D
Link status:             Connected
Cluster interface status: DOWN
CCP mode:                 Unicast

---- Unique IP's Table ----
Member      IP-Address      MAC-Address
-----
-----

Flags:
Link Monitored:          NO
Used:                    NO
Sync:                    NO
In Topology:              NO

[Expert@Member1:0]#
```

Description of the "cphaprob -a if ethX" command output fields:

| Field, or Text  | Description                                                                                                                                                                                                       |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Interface name  | Shows the name of the interface as assigned in the operating system.                                                                                                                                              |
| FW ifn          | Shows the internal interface number that ClusterXL assigned to this interface.                                                                                                                                    |
| IPv4 Address    | Shows the IPv4 address and the subnet mask configured on this interface. This field is empty if no IPv4 address is configured.                                                                                    |
| VIP             | Shows the IPv4 Cluster Virtual IP address and the subnet mask configured on this interface. This field is empty if no VIP address is configured.                                                                  |
| IPv6 Link Local | Shows the IPv6 link-local address configured on this interface. This field appears only when IPv6 is enabled in the Gaia operating system and such an IPv6 address is configured.                                 |
| IPv6 VIP        | Shows the IPv6 Cluster Virtual IP address and prefix length configured on this interface. This field appears only when IPv6 is enabled in the Gaia operating system and an IPv6 Virtual IP address is configured. |
| MAC Address     | Shows the physical MAC address of this interface.                                                                                                                                                                 |

| Field, or Text                  | Description                                                                                                                                                                                                                                                                                                                           |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VMAC Address</b>             | Shows the Virtual MAC address of this interface, if Virtual MAC is enabled.                                                                                                                                                                                                                                                           |
| <b>Link status</b>              | Shows the physical link state of the interface - "Connected" or "Not-Connected".                                                                                                                                                                                                                                                      |
| <b>Cluster interface status</b> | Shows the cluster state of this interface - "UP" or "DOWN".<br>Also shows the probing status while ClusterXL probes the network to determine the state of this interface.                                                                                                                                                             |
| <b>CCP mode</b>                 | Shows the CCP mode - "Unicast" (default), "Manual (Broadcast)", or "Manual (Multicast)".<br>The value "multi-ver" means this is a Multi-Version Cluster (MVC).                                                                                                                                                                        |
| <b>Unique IP's Table</b>        | Shows the unique IP address and MAC address of each peer interface on other Cluster Members.<br>The output does not show the local cluster member.<br>The "Member" column shows the internal index of the Cluster Member (the count starts from 0).<br>This table is empty when the cluster does not monitor the specified interface. |
| <b>Link Monitored</b>           | Shows whether ClusterXL monitors the physical link state of this interface - "YES" or "NO".                                                                                                                                                                                                                                           |
| <b>VLAN Monitored</b>           | Shows whether ClusterXL monitors this VLAN interface - "YES" or "NO".<br>This field appears only for a VLAN interface.                                                                                                                                                                                                                |
| <b>Bridge</b>                   | Shows whether this is a Bridge interface - "YES" or "NO".<br>This field appears only for a Bridge interface.                                                                                                                                                                                                                          |
| <b>Loopback</b>                 | Shows whether this is a Loopback interface - "YES" or "NO".<br>This field appears only for a Loopback interface.                                                                                                                                                                                                                      |
| <b>Used</b>                     | Shows whether ClusterXL monitors this interface - "YES" or "NO".<br>If this field shows "NO", then the output of the "cphaprob [-a] [-m] if" commands does not show this interface.                                                                                                                                                   |
| <b>Sync</b>                     | Shows whether this is a Sync interface - "YES" or "NO".                                                                                                                                                                                                                                                                               |
| <b>In Topology</b>              | Shows whether this interface is part of the cluster topology in the Management Server database.                                                                                                                                                                                                                                       |

# Viewing Bond Interfaces

## Description

This command shows the configuration of bond interfaces and their subordinate interfaces.

## Syntax

| Shell       | Command                                                                                                                                                         |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Gaia Clish  | <ol style="list-style-type: none"> <li>1. <code>show cluster bond {all   name &lt;bond_name&gt;}</code></li> <li>2. <code>show bonding groups</code></li> </ol> |
| Expert mode | <code>cphaprob show_bond [&lt;bond_name&gt;]</code><br><code>cphaprob show_bond_groups</code>                                                                   |

## Where:

| Command                                                                                                    | Description                                              |
|------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| <code>show cluster bond all</code><br><code>show bonding groups</code><br><code>cphaprob show_bond</code>  | Shows configuration of all configured bond interfaces    |
| <code>show cluster bond name &lt;bond_name&gt;</code><br><code>cphaprob show_bond &lt;bond_name&gt;</code> | Shows configuration of the specified bond interface      |
| <code>cphaprob show_bond_groups</code>                                                                     | Shows the configured Groups of Bonds and their settings. |

## Examples

### Example 1 - 'cphaprob show\_bond'

```
[Expert@Member2:0]# cphaprob show_bond
```

| Bond name | Mode              | State | Slaves configured | Slaves link up | Slaves required |
|-----------|-------------------|-------|-------------------|----------------|-----------------|
| bond1     | High Availability | UP    | 2                 | 2              | 1               |

```

Legend:
-----
UP!           - Bond interface state is UP, yet attention is required
Slaves configured - number of slave interfaces configured on the bond
Slaves link up   - number of operational slaves
Slaves required  - minimal number of operational slaves required for bond to be UP

[Expert@Member2:0]#

Member2> show bonding groups
Bonding Interface: 1
  Bond Configuration
    xmit-hash-policy Not configured
    down-delay 200
    primary Not configured
    lacp-rate Not configured
    mode active-backup
    up-delay 200
    mii-interval 100
  Bond Interfaces
    eth3
    eth4

Description of the output fields for the "cphaprob show\_bond" and "show cluster bond all" commands:

Table: Description of the output fields

| Field                    | Description                                                                                                                                                                                                                                  |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Bond name</b>         | Name of the Gaia bonding group.                                                                                                                                                                                                              |
| <b>Mode</b>              | Bonding mode of this Gaia bonding group.<br>One of these: <ul style="list-style-type: none"> <li>■ High Availability</li> <li>■ Load Sharing</li> </ul>                                                                                      |
| <b>State</b>             | State of the Gaia bonding group: <ul style="list-style-type: none"> <li>■ UP - Bond interface is fully operational</li> <li>■ UP! - Bond interface state is UP, yet attention is required</li> <li>■ DOWN - Bond interface failed</li> </ul> |
| <b>Slaves configured</b> | Total number of physical subordinate interfaces configured in this Gaia bonding group.                                                                                                                                                       |

Table: Description of the output fields (continued)

| Field                  | Description                                                                                                               |
|------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <b>Slaves link up</b>  | Number of operational physical subordinate interfaces in this Gaia bonding group.                                         |
| <b>Slaves required</b> | Minimum number of operational physical subordinate interfaces required for the state of this Gaia bonding group to be UP. |

**Example 2 - 'cphaprob show\_bond <bond\_name>'**

```
[Expert@Member2:0]# cphaprob show_bond bond1

Bond name:      bond1
Bond mode:      High Availability
Bond status:     UP

Configured slave interfaces: 2
In use slave interfaces:      2
Required slave interfaces:    1

Slave name      | Status      | Link
-----+-----+-----
eth4            | Active      | Yes
eth3            | Backup      | Yes

[Expert@Member2:0]#
```

Description of the output fields for the "cphaprob show\_bond <bond\_name>" and "show cluster bond name <bond\_name>" commands:

Table: Description of the output fields

| Field                              | Description                                                                                                                                                                                                                                                 |

Description of the output fields for the "cphaprob show\_bond\_groups" command:

Table: Description of the output fields

| Field                        | Description                                                                                                                                                                          |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Group of bonds name</b>   | Name of the Group of Bonds.                                                                                                                                                          |
| <b>State</b>                 | State of the Group of Bonds. One of these: <ul style="list-style-type: none"> <li>■ UP - Group of Bonds is fully operational</li> <li>■ DOWN - Group of Bonds failed</li> </ul>      |
| <b>Required active bonds</b> | Number of required active bonds in this Group of Bonds.                                                                                                                              |
| <b>Bonds in group</b>        | Names of the Gaia bond interfaces configured in this Group of Bonds.                                                                                                                 |
| <b>Bonds status</b>          | State of the Gaia bond interface. One of these: <ul style="list-style-type: none"> <li>■ UP - Bond interface is fully operational</li> <li>■ DOWN - Bond interface failed</li> </ul> |

# Viewing Cluster Failover Statistics

## Description

This command shows the cluster failover statistics on the Cluster Member:

- Number of failovers that happened
- Failover reason
- The time of the last failover event

## Syntax to show the statistics

| Shell       | Command                                                 |
|-------------|---------------------------------------------------------|
| Gaia Clish  | <code>show cluster failover</code>                      |
| Expert mode | <code>cphaprob [-l &lt;number&gt;] show_failover</code> |

## Syntax to reset the statistics

| Shell       | Command                                                    |
|-------------|------------------------------------------------------------|
| Gaia Clish  | <code>show cluster failover reset {count   history}</code> |
| Expert mode | <code>cphaprob -reset {-c   -h} show_failover</code>       |

## Parameters

| Parameter                               | Description                                                           |
|-----------------------------------------|-----------------------------------------------------------------------|
| <code>-l &lt;number&gt;</code>          | Specifies how many of last failover events to show (between 1 and 50) |
| <code>count</code><br><code>-c</code>   | Resets the counter of failover events                                 |
| <code>history</code><br><code>-h</code> | Resets the history of failover events                                 |

Example

```
[Expert@Member1:0]# cphaprob show_failover

Last cluster failover event:
  Transition to new ACTIVE:  Member 2 -> Member 1
  Reason:                   ADMIN_DOWN PNOTE
  Event time:               Sun Sep  8 18:21:44 2019

Cluster failover count:
  Failover counter:         1
  Time of counter reset:    Sun Sep  8 16:08:34 2019 (reboot)

Cluster failover history (last 20 failovers since reboot/reset on Sun Sep  8 16:08:34 2019):

No. Time:                Transition:                CPU: Reason:
-----
1   Sun Sep  8 18:21:44 2019  Member 2 -> Member 1  01   ADMIN_DOWN PNOTE

[Expert@Member1:0]#
```

# Viewing Software Versions on Cluster Members

## Description

This command shows information about the software version (including private hotfixes) on the local Cluster Member and its matches / mismatches with other Cluster Members.

## Syntax

| Shell       | Command                           |
|-------------|-----------------------------------|
| Gaia Clish  | <code>show cluster release</code> |
| Expert mode | <code>cphaprob release</code>     |

## Example

```
[Expert@Member1:0]# cphaprob release

Release:                R80.40 T136

Kernel build:           994000117
FW1 build:               994000116
FW1 private fixes:      None

ID          SW release

1 (local)   R80.40 T136
2           R80.40 T136

[Expert@Member1:0]#
```

## Viewing Delta Synchronization

Heavily loaded clusters and clusters with geographically separated members pose special challenges.

High connection rates, and large distances between the members can lead to delays that affect the operation of the cluster.

Monitor the operation of the State Synchronization mechanism in highly loaded and distributed clusters.

### Perform these troubleshooting steps:

1. Examine the Delta Sync statistics counters:

| Shell       | Command                                   |
|-------------|-------------------------------------------|
| Gaia Clish  | <code>show cluster statistics sync</code> |
| Expert mode | <code>cphaprob syncstat</code>            |

2. Change the values of the applicable synchronization global configuration parameters.
3. Reset the Delta Sync statistics counters:

| Shell       | Command                                         |
|-------------|-------------------------------------------------|
| Gaia Clish  | <code>show cluster statistics sync reset</code> |
| Expert mode | <code>cphaprob -reset syncstat</code>           |

4. Examine the Delta Sync statistics to see if the problem is solved.
5. Solve any identified problem.

## Example output of the "show cluster statistics sync" and "cphaprob syncstat" commands from a Cluster Member:

```
Delta Sync Statistics

Sync status: OK

Drops:
Lost updates..... 0
Lost bulk update events..... 0
Oversized updates not sent..... 0

Sync at risk:
Sent reject notifications..... 0
Received reject notifications..... 0

Sent messages:
Total generated sync messages..... 26079
Sent retransmission requests..... 0
Sent retransmission updates..... 0
Peak fragments per update..... 1

Received messages:
Total received updates..... 3710
Received retransmission requests..... 0

Sync Interface:
Name..... eth1
Link speed..... 1000Mb/s
Rate..... 46000 [Bps]
Peak rate..... 46000 [Bps]
Link usage..... 0%
Total..... 376827 [KB]

Queue sizes (num of updates):
Sending queue size..... 512
Receiving queue size..... 256
Fragments queue size..... 50

Timers:
Delta Sync interval (ms)..... 100

Reset on Sun Sep  8 16:09:15 2019 (triggered by fullsync).
```

Each section of the output is described below.

### The "Sync status:" section

This section shows the status of the Delta Sync mechanism. One of these:

- Sync status: OK
- Sync status: Off - Full-sync failure
- Sync status: Off - Policy installation failure
- Sync status: Off - Cluster module not started
- Sync status: Off - SIC failure
- Sync status: Off - Full-sync checksum error
- Sync status: Off - Full-sync received queue is full

- Sync status: Off - Release version mismatch
- Sync status: Off - Connection to remote member timed-out
- Sync status: Off - Connection terminated by remote member
- Sync status: Off - Could not start a connection to remote member
- Sync status: Off - cpstart
- Sync status: Off - cpstop
- Sync status: Off - Manually disabled sync
- Sync status: Off - Was not able to start for more than X second
- Sync status: Off - Boot
- Sync status: Off - Connectivity Upgrade (CU)
- Sync status: Off - cphastop
- Sync status: Off - Policy unloaded
- Sync status: Off - Hibernation
- Sync status: Off - OSU deactivated
- Sync status: Off - Sync interface down
- Sync status: Fullsync in progress
- Sync status: Problem (Able to send sync packets, unable to receive sync packets)
- Sync status: Problem (Able to send sync packets, saving incoming sync packets)
- Sync status: Problem (Able to send sync packets, able to receive sync packets)
- Sync status: Problem (Unable to send sync packets, unable to receive sync packets)
- Sync status: Problem (Unable to send sync packets, saving incoming sync packets)
- Sync status: Problem (Unable to send sync packets, able to receive sync packets)

### The "Drops:" section

This section shows statistics for drops on the Delta Sync network.

Table: Description of the output fields

| Field                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Lost updates</b>               | <p>Shows how many Delta Sync updates this Cluster Member considers as lost (based on sequence numbers in CCP packets).<br/>If this counter shows a value greater than 0, this Cluster Member lost Delta Sync updates.</p> <p><b>Possible mitigation:</b><br/>Increase the size of the Sending Queue and the size of the Receiving Queue:</p> <ul style="list-style-type: none"> <li>▪ Increase the size of the Sending Queue, if the counter <b>Received reject notification</b> is increasing.</li> <li>▪ Increase the size of the Receiving Queue, if the counter <b>Received reject notification</b> is not increasing.</li> </ul>                                                                                                                                                                                                                                                                                    |
| <b>Lost bulk update events</b>    | <p>Shows how many times this Cluster Member missed Delta Sync updates. (bulk update = twice the size of the local receiving queue)<br/>This counter increases when this Cluster Member receives a Delta Sync update with a sequence number much greater than expected. This probably indicates some networking issues that cause massive packet drops.</p> <p>This counter increases when the amount of missed Delta Sync updates is more than twice the local Receiving Queue Size.</p> <p><b>Possible mitigation:</b></p> <ul style="list-style-type: none"> <li>▪ If the counter's value is steady, this might indicate a one-time synchronization problem that can be resolved by running manual Full Sync. See <a href="#">sk37029</a>.</li> <li>▪ If the counter's value keeps increasing, probable there are some networking issues. Increase the sizes of both the Receiving Queue and Sending Queue.</li> </ul> |
| <b>Oversized updates not sent</b> | <p>Shows how many oversized Delta Sync updates were discarded before sending them.<br/>This counter increases when Delta Sync update is larger than the local Fragments Queue Size.</p> <p><b>Possible mitigation:</b></p> <ul style="list-style-type: none"> <li>▪ If the counter's value is steady, increase the size of the Sending Queue.</li> <li>▪ If the counter's value keeps increasing, contact <a href="#">Check Point Support</a>.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

### The "Sync at risk:" section

This section shows statistics that the Sending Queue is at full capacity and rejects Delta Sync retransmission requests.

Table: Description of the output fields

| Field                               | Description                                                                                                                                                                                            |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Sent reject notifications</b>    | Shows how many times this Cluster Member rejected Delta Sync retransmission requests from its peer Cluster Members, because this Cluster Member does not hold the requested Delta Sync update anymore. |
| <b>Received reject notification</b> | Shows how many reject notifications this Cluster Member received from its peer Cluster Members.                                                                                                        |

### The "Sent updates:" section

This section shows statistics for Delta Sync updates sent by this Cluster Member to its peer Cluster Members.

Table: Description of the output fields

| Field                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Total generated sync messages</b> | Shows how many Delta Sync updates were generated. This counts the Delta Sync updates, Retransmission Requests, Retransmission Acknowledgments, and so on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Sent retransmission requests</b>  | Shows how many times this Cluster Member asked its peer Cluster Members to retransmit specific Delta Sync update(s). Retransmission requests are sent when certain Delta Sync updates (with a specified sequence number) are missing, while the sending Cluster Member already received Delta Sync updates with advanced sequences.<br><b>Note</b> - Compare the number of <b>Sent retransmission requests</b> to the <b>Total generated sync messages</b> of the other Cluster Members. A large counter's value can imply connectivity problems. If the counter's value is unreasonably high (more than 30% of the <b>Total generated sync messages</b> of other Cluster Members), contact <a href="#">Check Point Support</a> equipped with the entire output and a detailed description of the network topology and configuration. |
| <b>Sent retransmission updates</b>   | Shows how many times this Cluster Member retransmitted specific Delta Sync update(s) at the requests from its peer Cluster Members.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

Table: Description of the output fields (continued)

| Field                            | Description                                                                                              |
|----------------------------------|----------------------------------------------------------------------------------------------------------|
| <b>Peak fragments per update</b> | Shows the peak amount of fragments in the Fragments Queue on this Cluster Member (usually, should be 1). |

### The "Received updates:" section

This section shows statistics for Delta Sync updates that were received by this Cluster Member from its peer Cluster Members.

Table: Description of the output fields

| Field                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Total received updates</b>           | Shows the total number of Delta Sync updates this Cluster Member received from its peer Cluster Members.<br>This counts only Delta Sync updates (not Retransmission Requests, Retransmission Acknowledgments, and others).                                                                                                                                                                                                                       |
| <b>Received retransmission requests</b> | Shows how many retransmission requests this Cluster Member received from its peer Cluster Members.<br>A large counter's value can imply connectivity problems. If the counter's value is unreasonably high (more than 30% of the <b>Total generated sync messages</b> on this Cluster Member), contact <a href="#">Check Point Support</a> equipped with the entire output and a detailed description of the network topology and configuration. |

### The "Queue sizes (num of updates):" section

This section shows the sizes of the Delta Sync queues.

Table: Description of the output fields

| Field                     | Description                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Sending queue size</b> | Shows the size of the cyclic queue, which buffers all the Delta Sync updates that were already sent until it receives an acknowledgment from the peer Cluster Members.<br>This queue is needed for retransmitting the requested Delta Sync updates.<br>Each Cluster Member has one Sending Queue.<br>Default: 512 Delta Sync updates, which is also the minimum value. |

Table: Description of the output fields (continued)

| Field                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Receiving queue size</b> | <p>Shows the size of the cyclic queue, which buffers the received Delta Sync updates in two cases:</p> <ul style="list-style-type: none"> <li>■ When Delta Sync updates are missing, this queue is used to hold the remaining received Delta Sync updates until the lost Delta Sync updates are retransmitted (Cluster Members must keep the order, in which they save the Delta Sync updates in the kernel tables).</li> <li>■ This queue is used to re-assemble a fragmented Delta Sync update.</li> </ul> <p>Each Cluster Member has one Receiving Queue.<br/>Default: 256 Delta Sync updates, which is also the minimum value.</p> |
| <b>Fragments queue size</b> | <p>Shows the size of the queue, which is used to prepare a Delta Sync update before moving it to the Sending Queue.</p> <p>Notes:</p> <ul style="list-style-type: none"> <li>■ This queue must be smaller than the Sending Queue.</li> <li>■ This queue must be significantly smaller than the Receiving Queue.</li> </ul> <p>Default: 50 Delta Sync updates, which is also the minimum value.</p>                                                                                                                                                                                                                                     |

**The "Timers:" section**

This section shows the Delta Sync timers.

| Field                           | Description                                                                                                                                                                                                                                                     |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Delta Sync interval (ms)</b> | <p>Shows the interval at which this Cluster Member sends the Delta Sync updates from its Sending Queue.<br/>The base time unit is 100ms (or 1 <i>tick</i>).<br/>Default: 100 ms, which is also the minimum value.<br/><i>See Increasing the Sync Timer.</i></p> |

**The "Reset on XXX (triggered XXX)" section**

Shows the date and the time of last statistics reset.

In parentheses, it shows how the last statistics was triggered - "manually", or "by fullsync".

# Viewing IGMP Status

## Description

This command shows the IGMP membership status.

## Syntax

| Shell       | Command                   |
|-------------|---------------------------|
| Gaia Clish  | show cluster members igmp |
| Expert mode | cphaprob igmp             |

## Example

```
[Expert@Member1:0]# cphaprob igmp

IGMP Membership: Enabled
Supported Version: 2
Report Interval [sec]: 60

IGMP queries are replied only by Operating System

Interface          Host Group      Multicast Address  Last ver.  Last Query[sec]
-----
eth0                224.168.3.247   01:00:5e:28:03:f7  N/A        N/A
eth1                224.22.33.250   01:00:5e:16:21:fa  N/A        N/A
eth2                224.55.66.247   01:00:5e:37:42:f7  N/A        N/A

[Expert@Member1:0]#
```

# Viewing Cluster Delta Sync Statistics for Connections Table

## Description

This command shows Delta Sync statistics about the operations performed in the Connections Kernel Table (id 8158).

The output shows operations such as creating a new connection (`SET`), updating a connection (`REFRESH`), deleting a connection (`DELETE`), and so on.

## Syntax

| Shell       | Command                                                |
|-------------|--------------------------------------------------------|
| Gaia Clish  | <code>show cluster statistics transport [reset]</code> |
| Expert mode | <code>cphaprob [-reset] ldstat</code>                  |

The `"reset"` flag resets the kernel statistics, which were collected since the last reboot or reset.

## Example

```
[Expert@Member1:0]# cphaprob ldstat
```

| Operand            | Calls | Bytes | Average | Ratio % |
|--------------------|-------|-------|---------|---------|
| -----              | ----- | ----- | -----   | -----   |
| ERROR              | 0     | 0     | 0       | 0       |
| SET                | 354   | 51404 | 145     | 33      |
| RENAME             | 0     | 0     | 0       | 0       |
| REFRESH            | 1359  | 70668 | 52      | 46      |
| DELETE             | 290   | 10440 | 36      | 6       |
| SLINK              | 193   | 12352 | 64      | 8       |
| UNLINK             | 0     | 0     | 0       | 0       |
| MODIFYFIELDS       | 91    | 7280  | 80      | 4       |
| RECORD DATA CONN   | 0     | 0     | 0       | 0       |
| COMPLETE DATA CONN | 0     | 0     | 0       | 0       |

```
Total bytes sent: 161292 (0 MB) in 1797 packets. Average 89
```

```
[Expert@Member1:0]#
```

# Viewing Cluster IP Addresses

## Description

This command shows the IP addresses and interfaces of the Cluster Members.

## Syntax to see all interfaces

| Shell       | Command                               |
|-------------|---------------------------------------|
| Gaia Clish  | <code>show cluster members ips</code> |
| Expert mode | <code>cphaprob tablestat</code>       |

## Syntax to see only the monitored interfaces

| Shell       | Command                                     |
|-------------|---------------------------------------------|
| Gaia Clish  | <code>show cluster members monitored</code> |
| Expert mode | <code>cphaprob -m tablestat</code>          |

## Example

 **Note** - To see name of interfaces that correspond to numbers in the "Interface" column, run the *["fw ctl iflist" on page 1135](#)* command.

```
[Expert@Member1:0]# cphaprob tablestat

---- Unique IP's Table ----
Member           Interface      IP-Address
-----
(Local)
0                 1              192.168.3.245
0                 2              11.22.33.245
0                 3              44.55.66.245

1                 1              192.168.3.246
1                 2              11.22.33.246
1                 3              44.55.66.246

-----

[Expert@Member1:0]#
[Expert@Member1:0]# fw ctl iflist
1 : eth0
2 : eth1
3 : eth2
[Expert@Member1:0]#
```

# Viewing the Cluster Member ID Mode in Local Logs

## Description

This command shows how the local ClusterXL logs show the Cluster Member - by its Member ID (default), or its Member Name.

See "[Configuring the Cluster Member ID Mode in Local Logs](#)" on page 1346.

## Syntax

| Shell       | Command                                  |
|-------------|------------------------------------------|
| Gaia Clish  | <code>show cluster members idmode</code> |
| Expert mode | <code>cphaprob names</code>              |

## Example

```
[Expert@Member1:0]# cphaprob names
Current member print mode in local logs is set to: ID
[Expert@Member1:0]#
```

# Viewing Interfaces Monitored by RouteD

## Description

This command shows the interfaces, which the RouteD daemon monitors on the Cluster Member when you configure OSPF.

The idea is that if you configure OSPF, Cluster Member monitors these interfaces and does not bring up the Cluster Member unless RouteD daemon says it is OK to bring up the Cluster Member. This is used mainly in ClusterXL High Availability Primary Up configuration to avoid premature failbacks.

## Syntax

| Shell       | Command                                      |
|-------------|----------------------------------------------|
| Gaia Clish  | <code>show ospf interfaces [detailed]</code> |
| Expert mode | <code>cphaprob routedifcs</code>             |

## Example 1

```
[Expert@Member1:0]# cphaprob routedifcs  
No interfaces are registered.  
[Expert@Member1:0]#
```

## Example 2

```
[Expert@Member1:0]# cphaprob routedifcs  
Monitored interfaces registered by routed:  
eth0  
[Expert@Member1:0]#
```

# Viewing Roles of RouteD Daemon on Cluster Members

## Description

This command shows on which Cluster Member the RouteD daemon runs as a Master.

### Notes:

- In ClusterXL High Availability, the RouteD daemon must run as a *Master* only on the Active Cluster Member.
- In ClusterXL Load Sharing, the RouteD daemon must run as a *Master* only on one of the Active Cluster Members and as a Non-Master on all other Cluster Members.
- In VRRP Cluster, the RouteD daemon must run as a *Master* only on the VRRP Master Cluster Member.

## Syntax

| Shell       | Command                        |
|-------------|--------------------------------|
| Gaia Clish  | <code>show cluster role</code> |
| Expert mode | <code>cphaprob roles</code>    |

## Example

```
[Expert@Member1:0]# cphaprob roles

ID          Role
1 (local)   Master
2           Non-Master

[Expert@Member1:0]#
```

# Viewing Cluster Correction Statistics

## Background

The Cluster Correction Layer (CCL) is a mechanism that deals with asymmetric connections - when a client-to-server connection passes through one Cluster Member, and the server-to-client connection arrives at another Cluster Member.

The CCL provides stickiness for connections by "correcting" the packets to the correct Cluster Member (that processed the client-to-server connection):

- In most cases, the CCL makes the correction from the CoreXL SND instances.
- In some cases (like Dynamic Routing, or VPN), the CCL makes the correction from the CoreXLFirewall instances or from SecureXL.

 **Note** - For more information about CoreXL, see the [R82.10 Performance Tuning Administration Guide](#).

## Description

This command shows the statistics counters for the Cluster Correction Layer (CCL) on each Cluster Member.

The counters are reset in these cases:

- During each boot.
- When Check Point services are stopped and started.

## Syntax

| Shell       | Command                                     |
|-------------|---------------------------------------------|
| Gaia Clish  | N / A                                       |
| Expert mode | <code>cphaprob [{-d   -f   -s}] corr</code> |

Where:

| Command                       | Description                                                             |
|-------------------------------|-------------------------------------------------------------------------|
| <code>cphaprob corr</code>    | Shows Cluster Correction Statistics for all traffic.                    |
| <code>cphaprob -d corr</code> | Shows Cluster Correction Statistics for CoreXL SND instances only.      |
| <code>cphaprob -f corr</code> | Shows Cluster Correction Statistics for CoreXL Firewall instances only. |
| <code>cphaprob -s corr</code> | Shows Cluster Correction Statistics for SecureXL only.                  |

#### Notes:

- In the output of "`cphaprob -d corr`", this row does not appear:  
Local asymmetric conns:
- In the output, these rows appear only on Scalable Platforms:
  - ICMP ERROR forwarded packets:
  - ICMP ERROR forwarded bytes:
  - VS Stateless forwarded packets:
  - VS Stateless forwarded bytes:
- In some cases, ClusterXL needs to send some data along with the corrected packet (for example, in VPN).  
For such packets, the output counters show "with metadata".

**Example 1 - CCL statistics for all traffic**

```
[Expert@Member1:0]# cphaprob corr

Cluster Correction Stats (All Traffic):
-----

Corrected sent bytes (% of total TX bytes):          140,053 (0.007%)
Corrected sent packets (% of total TX packets):      772 (0.032%)
  via simple correction:                             772
  via cpha correction:                               0
  corrected with metadata:                           0
  was fragmented by correction layer:                 0
  was corrected over Sync interface:                 772
Corrected received bytes (% of total RX bytes):      6,900,731 (0.321%)
Corrected received packets (% of total RX packets):  10642 (0.435%)
  via simple correction:                             10642
  via cpha correction:                               0
  corrected with metadata:                           0
  was fragmented by correction layer:                 0
Errors while sending corrected packets:              0
Errors while receiving corrected packets :           0
Local asymmetric conns:                             103
ICMP ERROR forwarded packets:                       0
ICMP ERROR forwarded bytes:                         0
VS Stateless forwarded packets:                     0
VS Stateless forwarded bytes:                       0

# Viewing the Cluster Control Protocol (CCP) Settings

## Description

- You can view the Cluster Control Protocol (CCP) mode on the Cluster Members.
- You can view the Cluster Control Protocol (CCP) Encryption on the Cluster Members - enabled or disabled (and the encryption key).

See ["Configuring the Cluster Control Protocol \(CCP\) Settings" on page 1357](#)

## Syntax for viewing the Cluster Control Protocol (CCP) mode

| Shell       | Command                                              |
|-------------|------------------------------------------------------|
| Gaia Clish  | <code>show cluster members interfaces virtual</code> |
| Expert mode | <code>cphaprob -a if</code>                          |

**Important** - In R82.10, the CCP always runs in the unicast mode.

## Syntax for viewing the Cluster Control Protocol (CCP) Encryption

| Shell       | Command                                                                    |
|-------------|----------------------------------------------------------------------------|
| Gaia Clish  | <code>show cluster members ccpenc</code>                                   |
| Expert mode | <code>cphaprob ccp_encrypt</code><br><code>cphaprob ccp_encrypt_key</code> |

# Viewing the State of the Multi-Version Cluster Mechanism

## Description

This command shows the state of the Multi-Version Cluster (MVC) Mechanism - enabled (ON) or disabled (OFF).

See ["Configuring the Multi-Version Cluster Mechanism" on page 1368](#).

## Syntax

| Shell       | Command                               |
|-------------|---------------------------------------|
| Gaia Clish  | <code>show cluster members mvc</code> |
| Expert mode | <code>cphaprob mvc</code>             |

## Example

```
Member1> show cluster members mvc  
  
ON  
  
Member1>
```

# Viewing Full Connectivity Upgrade Statistics

## Description

This command shows the Full Connectivity Upgrade statistics when you upgrade between minor versions.

## Syntax

| Shell       | Command          |
|-------------|------------------|
| Gaia Clish  | N / A            |
| Expert mode | cphaprob fcustat |

## Example

```
[Expert@Member1:0]# cphaprob fcustat

During FCU..... no
Connection module map..... none

Table id map (remote->local)..... none

Table handlers .....
    8151 --> 0x0x7f97c421d860 (sip_state)
    8158 --> 0x0x7f97c43d8e30 (connections)
LD handlers.....
    ok - 0
    failed - 0

Global handlers ..... none

[Expert@Member1:0]#
```

# cpconfig

## Description

This command starts the Check Point Configuration Tool.

This tool configures specific settings for the installed Check Point products.

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.

## Syntax on a Security Gateway / Cluster Member in Gaia Clish or the Expert mode

```
cpconfig
```

## Syntax on a Scalable Platform Security Group in Gaia gClish or the Expert mode

```
cpconfig
```

## Menu Options

 **Note** - The options shown depend on the configuration and installed products.

| Menu Option            | Description                                                                                                                                                                                |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Licenses and contracts | Manages Check Point licenses and contracts on this Security Gateway or Cluster Member.                                                                                                     |
| SNMP Extension         | Obsolete. Do <b>not</b> use this option anymore.<br>To configure SNMP, see the <a href="#">R82.10 Gaia Administration Guide</a> - Chapter <i>System Management</i> - Section <i>SNMP</i> . |
| PKCS#11 Token          | Register a cryptographic token, for use by Gaia Operating System.<br>See details of the token, and test its functionality.                                                                 |
| Random Pool            | Configures the RSA keys, to be used by Gaia Operating System.                                                                                                                              |

| Menu Option                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Exit                                                    | Exits from the Check Point Configuration Tool.                                                                                                                                                                                                                                                                                                                                                                                           |

## Example 1 - Menu on a single Security Gateway

```
[Expert@MySingleGW:0]# cpconfig
This program will let you re-configure
your Check Point products configuration.

Configuration Options:
-----
(1) Licenses and contracts
(2) SNMP Extension
(3) PKCS#11 Token
(4) Random Pool
(5) Secure Internal Communication
(6) Enable cluster membership for this gateway
(7) Check Point CoreXL
(8) Automatic start of Check Point Products

(9) Exit

Enter your choice (1-9) :
```

## Example 2 - Menu on a Cluster Member

```
[Expert@MyClusterMember:0]# cpconfig
This program will let you re-configure
your Check Point products configuration.

Configuration Options:
-----
(1) Licenses and contracts
(2) SNMP Extension
(3) PKCS#11 Token
(4) Random Pool
(5) Secure Internal Communication
(6) Disable cluster membership for this gateway
(7) Enable Check Point Per Virtual System State
(8) Enable Check Point ClusterXL for Bridge Active/Standby
(9) Check Point CoreXL
(10) Automatic start of Check Point Products

(11) Exit

Enter your choice (1-11) :
```

# cphastart

## Description

Starts the cluster configuration on a Cluster Member after it was stopped with the ["cphastop" on page 1435](#) command.

- ★ **Best Practice** - To start a Cluster Member, use the ["cpstart" on page 1032](#) command.
- 📘 **Note** - This command does **not** initiate a Full Synchronization on the Cluster Member.

## Syntax

```
cphastart
      [-h]
      [-d]
```

## Parameters

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

# cphastop

## Description

Stops the cluster software on a Cluster Member.

**Best Practice** - To stop a Cluster Member, use the *"cpstop" on page 1043* command.

### Notes:

- This command stops the Cluster Member from passing traffic.
- This command stops the State Synchronization between this Cluster Member and its peer Cluster Members.
- After you run this command, you can still open connections directly to this Cluster Member.
- To start the cluster software, run the *"cphastart" on page 1434* command.

## Syntax

```
cphastop
```

# cp\_conf fullha

 **Important** - This command does **not** apply to Scalable Platforms (Maestro and Chassis).

## Description

Manages the state of the Full High Availability Cluster:

- Enables the Full High Availability Cluster
- Disables the Full High Availability Cluster
- Deletes the Full High Availability peer
- Shows the Full High Availability state

 **Important** - To configure a Full High Availability cluster, follow the [R82.10 Installation and Upgrade Guide](#).

## Syntax

```
cp_conf fullha
    enable
    del_peer
    disable
    state
```

## Parameters

| Parameter | Description                                                     |
|-----------|-----------------------------------------------------------------|
| enable    | Enables the Full High Availability on this computer.            |
| del_peer  | Deletes the Full High Availability peer from the configuration. |
| disable   | Disables the Full High Availability on this computer.           |
| state     | Shows the Full High Availability state on this computer.        |

## Example

```
[Expert@Cluster_Member:0]# cp_conf fullha state
FullHA is currently enabled
[Expert@Cluster_Member:0]#
```

# cp\_conf ha

 **Important** - This command does **not** apply to Scalable Platforms (Maestro and Chassis).

## Description

Enables or disables cluster membership on this Security Gateway.

 **Important** - This command is for Check Point use only. To configure cluster membership, you must use the ["cpconfig" on page 1002](#) command. For more information, see the [R82.10 ClusterXL Administration Guide](#).

## Syntax

```
cp_conf ha {enable | disable} [norestart]
```

## Parameters

| Parameter | Description                                                                                                                                                                                            |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| enable    | Enables cluster membership on this Security Gateway. This command is equivalent to the option <b>Enable cluster membership for this gateway</b> in the <a href="#">"cpconfig" on page 1002</a> menu.   |
| disable   | Disables cluster membership on this Security Gateway. This command is equivalent to the option <b>Disable cluster membership for this gateway</b> in the <a href="#">"cpconfig" on page 1002</a> menu. |
| norestart | <b>Optional:</b> Specifies to apply the configuration change without the restart of Check Point services. The new configuration takes effect only after reboot.                                        |

## Example 1 - Enable the cluster membership without restart of Check Point services

```
[Expert@MyGW:0]# cp_conf ha enable norestart

Cluster membership for this gateway was enabled successfully
Important: This change will take effect after reboot.

[Expert@MyGW:0]#
```

## Example 2 - Disable the cluster membership without restart of Check Point services

```
[Expert@MyGW:0]# cp_conf ha disable norestart
cpwd_admin:
Process CPHAMCSET process has been already terminated

Cluster membership for this gateway was disabled successfully
Important: This change will take effect after reboot.

[Expert@MyGW:0]#
```

# fw hastat

## Description

Shows information about Check Point computers in High Availability configuration and their states.

-  **Note** - This command is outdated. On cluster members, run the Gaia Clish command "show cluster state", or the Expert mode command "cphaprob state".
-  **Note** - This command is outdated. On Management Servers, run the ["cpstat" on page 209](#) command.

## Syntax

```
fw hastat [<Target1>] [<Target2>] ... [<TargetN>]
```

## Parameters

| Parameter                               | Description                                                                                                                                                                                                                                                                                            |
|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <Target1><br><Target2> ...<br><TargetN> | Specifies the Check Point computers to query.<br>If you run this command on the Management Server, you can enter the applicable IP address, or the resolvable HostName of the managed Security Gateway or Cluster Member.<br>If you do not specify the target, the command queries the local computer. |

## Example - Querying the cluster members from the Management Server

```
[Expert@MGMT:0]# fw hastat 192.168.3.52
HOST NUMBER HIGH AVAILABILITY STATE MACHINE STATUS
192.168.3.52 1 active OK
[Expert@MGMT:0]#

[Expert@MGMT:0]# fw hastat 192.168.3.53
HOST NUMBER HIGH AVAILABILITY STATE MACHINE STATUS
192.168.3.53 2 stand-by OK
[Expert@MGMT:0]#

[Expert@MGMT:0]# fw hastat 192.168.3.52 192.168.3.53
HOST NUMBER HIGH AVAILABILITY STATE MACHINE STATUS
192.168.3.52 1 active OK
192.168.3.53 2 stand-by OK
[Expert@MGMT:0]#
```

## Example - Querying the local Cluster Member

```
[Expert@Member1:0]# fw hastat  
HOST NUMBER HIGH AVAILABILITY STATE MACHINE STATUS  
192.168.3.52 1 active OK  
[Expert@Member1:0]#
```

# fwboot ha\_conf

## Description

Configures the cluster mechanism during boot.

**Important** - This command is for Check Point use only.

### Notes:

- You must run this command from the Expert mode.
- Refer to these related commands:
  - ["fw defaultgen" on page 1152](#)
  - ["fwboot bootconf" on page 1300](#)
  - ["control\\_bootsec" on page 979](#)
  - ["comp\\_init\\_policy" on page 964](#)
- To install a cluster, see the [R82.10 Installation and Upgrade Guide](#).
- To configure a cluster, see the [R82.10 Installation and Upgrade Guide](#) and [R82.10 ClusterXL Administration Guide](#).

## Syntax

```
[Expert@HostName:0]# $FWDIR/boot/fwboot ha_conf
```

# The clusterXL\_admin Script

## Description

You can use the **clusterXL\_admin** script to initiate a manual fail-over from a Cluster Member.

Location of this script on your Cluster Members is:

```
$FWDIR/bin/clusterXL_admin
```

## Script Workflow

This shell script does one of these:

- Registers a Critical Device called "admin\_down" and reports the state of that Critical Device as "problem".

This gracefully changes the state of the Cluster Member to "DOWN".

- Reports the state of the registered Critical Device "admin\_down" as "ok".

This gracefully changes the state of the Cluster Member to "UP".

Then, the script unregisters the Critical Device "admin\_down".

For more information, see [sk55081](#).

## Example

```

#!/bin/csh -f
#
# The script will cause the machine to get into down state, thus the member will not filter
# packets.
# It will supply a simple way to initiate a failover by registering a new device in problem
# state when
# a failover is required and will unregister the device when wanting to return to normal
# operation.
# USAGE:
# clusterXL_admin <up|down>

set PERSISTENT = ""

# checking number of arguments
if ( $#argv > 2 || $#argv < 1 ) then
    echo "clusterXL_admin : Invalid Argument Count"
    echo "Usage: clusterXL_admin <up|down> [-p]"
    exit 1
else if ( "$1" != "up" && "$1" != "down" ) then
    echo "clusterXL_admin : Invalid Argument ($1)"
    echo "Usage: clusterXL_admin <up|down> [-p]"
    exit 1
else if ( $#argv == 2 ) then
    if ( "$2" != "-p" ) then
        echo "clusterXL_admin : Invalid Argument ($2)"
        echo "Usage: clusterXL_admin <up|down> [-p]"
        exit 1
    endif
    set PERSISTENT = "-p"
endif

#checking if cpha is started
$FWDIR/bin/cphaprob stat | grep "Cluster" > /dev/null
if ($status) then
    echo "HA is not started"
    exit 1
endif

# Inform the user that the command can run with persistent mode.
if (" $PERSISTENT" != "-p") then
    echo "This command does not survive reboot. To make the change permanent, please run
'set cluster member admin down/up permanent' in clish or add '-p' at the end of the command in
expert mode"
endif

if ( $1 == "up" ) then
    echo "Setting member to normal operation ..."
    $FWDIR/bin/cphaconf set_pnote -d admin_down $PERSISTENT unregister > & /dev/null
    if ( `uname` == 'IPSO' ) then
        sleep 5
    else
        sleep 1
    endif

    set stateArr = `$FWDIR/bin/cphaprob stat | grep "local"`

    $FWDIR/bin/cphaprob stat | egrep "Sync only|Bridge Mode" > /dev/null

        echo "All the members within the cluster have problem/s and the local member was
chosen to become active"
    else
        if ( $state != "Down" && $state != "DOWN" ) then
            echo "Operation failed: member is still down, please run 'show cluster
members pnotes problem' in clish or 'cphaprob list' in expert mode for further details"
        endif
    endif
    exit 0
else
    echo "clusterXL_admin : Invalid Option ($1)"
    echo "Usage: clusterXL_admin <up|down> [-p]"
    exit 1
endif

```

# The clusterXL\_monitor\_ips Script

## Description

You can use the `clusterXL_monitor_ips` script to ping a list of predefined IP addresses and change the state of the Cluster Member to `DOWN` or `UP` based on the replies to these pings. For this script to work, you must write the IP addresses in the `$FWDIR/conf/cpha_hosts` file - each IP address on a separate line. This file does not support comments or spaces.

Location of this script on your Cluster Members is:

```
$FWDIR/bin/clusterXL_monitor_ips
```

## Script Workflow

1. Registers a Critical Device called "host\_monitor" with the status "ok".
2. Starts to send pings to the list of predefined IP addresses in the `$FWDIR/conf/cpha_hosts` file.
3. While the script receives responses to its pings, it does not change the status of that Critical Device.
4. If the script does not receive a response to even one ping, it reports the state of that Critical Device as "problem".

This gracefully changes the state of the Cluster Member to `DOWN`.

If the script receives responses to its pings again, it changes the status of that Critical Device to "ok" again.

For more information, see [sk35780](#).

**Important** - You must do these changes on all Cluster Members.

## Example

```
#!/bin/sh
#
# The script tries to ping the hosts written in the file $FWDIR/conf/cpha_hosts. The names (must
be resolveable) of the IPs of the hosts must be written in separate lines.
# the file must not contain anything else.
# We ping the given hosts every number of seconds given as parameter to the script.
# USAGE:
# cpha_monitor_ips X silent
# where X is the number of seconds between loops over the IPs.
# if silent is set to 1, no messages will appear on the console
#
# We initially register a pnote named "host_monitor" in the problem notification mechanism
# when we detect that a host is not responding we report the pnote to be in "problem" state.
# when ping succeeds again - we report the pnote is OK.

silent=0

    sleep $1
    echo "sleep $1"
done
```

# The clusterXL\_monitor\_process Script

## Description

You can use the **clusterXL\_monitor\_process** script to monitor if the specified user space processes run, and cause cluster fail-over if these processes do not run. For this script to work, you must write the correct case-sensitive names of the monitored processes in the `$FWDIR/conf/cpha_proc_list` file - each process name on a separate line. This file does not support comments or spaces.

Location of this script on your Cluster Members is:

```
$FWDIR/bin/clusterXL_monitor_process
```

## Script Workflow

1. Registers Critical Devices (with the status "ok") called as the names of the processes you specified in the `$FWDIR/conf/cpha_proc_list` file.
2. While the script detects that the specified process runs, it does not change the status of the corresponding Critical Device.
3. If the script detects that the specified process do not run anymore, it reports the state of the corresponding Critical Device as "problem".

This gracefully changes the state of the Cluster Member to "DOWN".

If the script detects that the specified process runs again, it changes the status of the corresponding Critical Device to "ok" again.

For more information, see [sk92904](#).

**Important** - You must do these changes on all Cluster Members.

## Example

```

#!/bin/sh
#
# This script monitors the existance of processes in the system. The process names should be
# written
# in the $FWDIR/conf/cpha_proc_list file one every line.
#
# USAGE :
# cpha_monitor_process X silent
# where X is the number of seconds between process probings.
# if silent is set to 1, no messages will appear on the console.
#
#
# We initially register a pnote for each of the monitored processes
# (process name must be up to 15 charachters) in the problem notification mechanism.
# when we detect that a process is missing we report the pnote to be in "problem" state.
# when the process is up again - we report the pnote is OK.

if [ "$2" -le 1 ]

# cpview

## Overview of CPView

### Description

CPView is a text based built-in utility on a Check Point computer.

CPView Utility shows statistical data that contain both general system information (CPU, Memory, Disk space) and information for different Software Blades (only on a Security Gateway / ClusterXL / Scalable Platform Security Group).

The CPView continuously updates the data in easy to access views.

On a Security Gateway / ClusterXL / Scalable Platform Security Group, you can use this statistical data to monitor the performance.

For more information, see [sk101878](#).

### Syntax

```
cpview --help
```

## CPView User Interface

The CPView user interface has three sections:

| Section    | Description                                                                                                                                    |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| Header     | This view shows the time the statistics in the third view are collected. It updates when you refresh the statistics.                           |
| Navigation | This menu bar is interactive. Move between menus with the arrow keys and mouse.<br>A menu can have sub-menus and they show under the menu bar. |
| View       | This view shows the statistics collected in that view. These statistics update at the refresh rate.                                            |

## Using CPView

Use these keys to navigate the CPView:

| Key        | Description                                                                                                                 |
|------------|-----------------------------------------------------------------------------------------------------------------------------|
| Arrow keys | Moves between menus and views. Scrolls in a view.                                                                           |
| Home       | Returns to the <b>Overview</b> view.                                                                                        |
| Enter      | Changes to the <b>View Mode</b> .<br>On a menu with sub-menus, the <b>Enter</b> key moves you to the lowest level sub-menu. |
| Esc        | Returns to the <b>Menu Mode</b> .                                                                                           |
| Q          | Quits CPView.                                                                                                               |

Use these keys to change CPView interface options:

| Key | Description                                                                                          |
|-----|------------------------------------------------------------------------------------------------------|
| R   | Opens a window where you can change the refresh rate.<br>The default refresh rate is 2 seconds.      |
| W   | Changes between wide and normal display modes.<br>In wide mode, CPView fits the screen horizontally. |
| S   | Manually sets the number of rows or columns.                                                         |
| M   | Switches on/off the mouse.                                                                           |
| P   | Pauses and resumes the collection of statistics.                                                     |

Use these keys to save statistics, show help, and refresh statistics:

| Key       | Description                                                                                                                                         |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| C         | Saves the current page to a file. The file name format is:<br><code>cpview_&lt;ID of the cpview process&gt;.cap&lt;Number of the capture&gt;</code> |
| H         | Shows a tooltip with CPView options.                                                                                                                |
| Space bar | Immediately refreshes the statistics.                                                                                                               |

# 'fwaccel' and 'fwaccel6'

## Description

The "fwaccel" commands control the acceleration for IPv4 traffic.

The "fwaccel6" commands control the acceleration for IPv6 traffic.

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.

# fwaccel cfg

## Description

The "fwaccel cfg" command controls the SecureXL acceleration parameters (for IPv4 only).

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.
- In the VSNext mode / Traditional VSX mode, you must go to the context of an applicable Virtual Gateway / Virtual System.
  - In Gaia Clish, run: `set virtual-system <VSID>`
  - In the Expert mode, run: `vsenv <VSID>`
- These commands do not provide output. You cannot see the currently configured values.
- Changes made with these commands do **not** survive reboot.

## Syntax

### Syntax on a Security Gateway / ClusterXL - in Gaia Clish and the Expert mode

```
fwaccel cfg
  -h
  -a {<Number of Interface> | <Name of Interface> | reset}
  -b {on | off}
  -c <Number>
  -d <Number>
  -e <Number>
  -i {on | off}
  -l <Number>
  -m <Seconds>
  -p {on | off}
  -r <Number>
  -v <Seconds>
  -w {on | off}
```

## Syntax on a Scalable Platform Security Group - in Gaia gClish

```
fwaccel cfg
  -h
  -a {<Number of Interface> | <Name of Interface> | reset}
  -b {on | off}
  -c <Number>
  -d <Number>
  -e <Number>
  -i {on | off}
  -l <Number>
  -m <Seconds>
  -p {on | off}
  -r <Number>
  -v <Seconds>
  -w {on | off}
```

## Syntax on a Scalable Platform Security Group - in the Expert mode

```
g_fwaccel cfg
  -h
  -a {<Number of Interface> | <Name of Interface> | reset}
  -b {on | off}
  -c <Number>
  -d <Number>
  -e <Number>
  -i {on | off}
  -l <Number>
  -m <Seconds>
  -p {on | off}
  -r <Number>
  -v <Seconds>
  -w {on | off}
```

## Parameters

| Parameter | Description                         |
|-----------|-------------------------------------|
| -h        | Shows the applicable built-in help. |

| Parameter                                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

# fwaccel conns

## Description

The "fwaccel conns" and "fwaccel6 conns" commands show the list of the SecureXL connections on the local Security Gateway, or Cluster Member.

 **Warning** - If the number of concurrent connections is large, when you run these commands, they can consume memory and CPU at very high level (see [sk118716](#)).

 **Important:**

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.
- In the VSNext mode / Traditional VSX mode, you must go to the context of an applicable Virtual Gateway / Virtual System.
  - In Gaia Clish, run: `set virtual-system <VSID>`
  - In the Expert mode, run: `vsenv <VSID>`

## Syntax for IPv4

```
fwaccel conns
  -h
  -f <filter>
  -m <Number of Entries>
  -s
  -z
```

## Syntax for IPv6

```
fwaccel6 conns
  -h
  -f <Filter>
  -m <Number of Entries>
  -s
  -z
```

## Parameters

| Parameter | Description                         |
|-----------|-------------------------------------|
| -h        | Shows the applicable built-in help. |

| Parameter                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

# fwaccel dbg

## Description

The *fwaccel dbg* command controls the SecureXL debug. See ["SecureXL Debug Procedure" on page 1702](#).

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the Gaia Portal of the applicable Security Group.
- If you do **not** use the complete debug procedure with the "fw ctl kdebug" command, and SecureXL works in User Mode (UPPAK), then Security Gateway writes the debug outputs to these files:
  - \$FWDIR/log/fw.kelg - Processing of traffic in the Firewall module
  - /var/log/usim\_x86.elg - Processing of traffic in SecureXL
  - /var/log/messages - Processing of traffic in the ADP module (NVIDIA ConnectX 100G Cards)

## Syntax in Gaia Clish or the Expert mode on a Security Gateway / ClusterXL:

```
fwaccel dbg
  -h
  -m <Name of SecureXL Debug Module>
  all
  + <Debug Flags>
  - <Debug Flags>
  reset
  -f {"<5-Tuple Debug Filter>" | reset}
  list
  resetall
```

**Syntax in Gaia gClish on a Scalable Platform Security Group:**

```
fwaccel dbg
  -h
  -m <Name of SecureXL Debug Module>
  all
  + <Debug Flags>
  - <Debug Flags>
  reset
  -f {"<5-Tuple Debug Filter>" | reset}
  list
  resetall
```

**Syntax in the Expert mode on a Scalable Platform Security Group:**

```
g_fwaccel dbg
  -h
  -m <Name of SecureXL Debug Module>
  all
  + <Debug Flags>
  - <Debug Flags>
  reset
  -f {"<5-Tuple Debug Filter>" | reset}
  list
  resetall
```

**Parameters**

| Parameter                          | Description                                                                                                                 |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| -h                                 | Shows the applicable built-in help.                                                                                         |
| -m <Name of SecureXL Debug Module> | Specifies the name of the SecureXL debug module.<br>To see the list of available debug modules, run: <div>fwaccel dbg</div> |
| all                                | Enables all debug flags for the specified debug module.                                                                     |

| Parameter                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| + <Debug Flags>             | <p>Enables the specified debug flags for the specified debug module:</p> <p>Syntax:</p> <pre>+ Flag1 [Flag2 Flag3 ... FlagN]</pre> <p> <b>Note</b> - You must press the space bar key after the plus (+) character.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| - <Debug Flags>             | <p>Disables all debug flags for the specified debug module.</p> <p>Syntax:</p> <pre>- Flag1 [Flag2 Flag3 ... FlagN]</pre> <p> <b>Note</b> - You must press the space bar key after the minus (-) character.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| reset                       | Resets all debug flags for the specified debug module to their default state.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| -f "<5-Tuple Debug Filter>" | <p>Configures the debug filter to show only debug messages that contain the specified connection.</p> <p>The filter is a string of five numbers separated with commas:</p> <pre>"&lt;Source IP Address&gt;,&lt;Source Port&gt;,&lt;Destination IP Address&gt;,&lt;Destination Port&gt;,&lt;Protocol Number&gt;"</pre> <p> <b>Notes:</b></p> <ul style="list-style-type: none"> <li>■ You can configure only one debug filter at one time.</li> <li>■ You can use the asterisk "*" as a wildcard for an IP Address, Port number, or Protocol number.</li> <li>■ For more information, see <a href="#">IANA Service Name and Port Number Registry</a> and <a href="#">IANA Protocol Numbers</a>.</li> </ul> |
| -f reset                    | Resets the current debug filter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| list                        | Shows all enabled debug flags in all debug modules.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| resetall                    | Reset all debug flags for all debug modules to their default state.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Enabling SecureXL debug flags during boot

From R81.20, you can configure SecureXL debug to start during boot.

**Important** - In a Cluster, you must configure all the Cluster Members in the same way.

### Procedure

| Step | Instructions                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1    | Connect to the command line on the Security Gateway / each Cluster Member. On Scalable Platforms, you must connect to the Gaia Portal of the applicable Security Group.                                                                                                                                                                                                                                                                            |
| 2    | Log in to the Expert mode.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 3    | Create the require configuration files: <ul style="list-style-type: none"> <li>To collect the debug for IPv4 traffic:               <pre>touch \$FWDIR/conf/fwaccel_dbg_flags.cfg</pre> </li> <li>To collect the debug for IPv6 traffic:               <pre>touch \$FWDIR/conf/fwaccel6_dbg_flags.cfg</pre> </li> </ul>                                                                                                                            |
| 4    | Edit the applicable configuration file: <ul style="list-style-type: none"> <li>To collect the debug for IPv4 traffic:               <pre>vi \$FWDIR/conf/fwaccel_dbg_flags.cfg</pre> </li> <li>To collect the debug for IPv6 traffic:               <pre>vi \$FWDIR/conf/fwaccel6_dbg_flags.cfg</pre> </li> </ul>                                                                                                                                  |
| 5    | Configure the applicable debug modules and the debug flags (see <a href="#">R82.10 Security Gateway Guide</a> ).<br>Write each debug module and its flags on a separate line: <pre>&lt;Name of Debug Module #1&gt; &lt;Flag1&gt; &lt;Flag2&gt; &lt;Flag3&gt; ...<br/>&lt;FlagN&gt;<br/>&lt;Name of Debug Module #2&gt; &lt;Flag1&gt; &lt;Flag2&gt; &lt;Flag3&gt; ...<br/>&lt;FlagN&gt;</pre> Example: <pre>default conn nat<br/>pkt drop nat</pre> |
| 6    | Save the changes in the file and exit the editor.                                                                                                                                                                                                                                                                                                                                                                                                  |

| Step | Instructions                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Examples

## Example 1 - Default output

```
[Expert@MyGW:0]# fwaccel dbg
Usage: fwaccel dbg [-m <...>] [resetall | reset | list | all | +/- <flags>]
    -m <module>           - module of debugging
    -h                   - this help message
    resetall             - reset all debug flags for all modules
    reset                - reset all debug flags for module
    all                  - set all debug flags for module
    list                 - list all debug flags for all modules
    -f reset | "<5-tuple>" - filter debug messages
    + <flags>            - set the given debug flags
    - <flags>            - unset the given debug flags
```

Debug flags can be enabled at boot by adding them to  
 \$FWDIR/conf/fwaccel\_dbg\_flags.cfg and \$FWDIR/conf/fwaccel6\_dbg\_flags.cfg.  
 The file format is one line per module.

For example, to enable "tcp\_state" and "routing" for the "pkt" module:  
 echo "pkt tcp\_state routing" >> \$FWDIR/conf/fwaccel\_dbg\_flags.cfg

List of available modules and flags:

## Example 2 - Enabling and disabling of debug flags

```
[Expert@MyGW:0]# fwaccel dbg -m default + conn
Debug flags updated.
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dbg list

[Expert@MyGW:0]# fwaccel dbg list
Module: default (400)
conn

Module: db (0)

Module: api (0)

Module: pkt (0)

Module: infras (0)

Module: tmpl (0)

Module: vpn (0)

Module: nac (0)

Module: cpaq (0)

Module: synatk (0)

Module: adp (0)

Module: dos (0)

Module: gtp (0)

Module: usdisp (0)

Module: dpdk_lib (0)

Module: dpdk_pmd (0)

Module: dpdk_other (0)

Debug filter not set.
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dbg -m default - conn
Debug flags updated.
[Expert@MyGW:0]#
```

```
[Expert@MyGW:0]# fwaccel dbg list

Module: default (0)

Module: db (0)

Module: api (0)

Module: pkt (0)

Module: infras (0)

Module: tmpl (0)

Module: vpn (0)

Module: nac (0)

Module: cpaq (0)

Module: synatk (0)

Module: adp (0)

Module: dos (0)

Module: gtp (0)

Module: usdisp (0)

Module: dpdk_lib (0)

Module: dpdk_pmd (0)

Module: dpdk_other (0)

Debug filter not set.
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dbg -m default reset
Debug flags updated.
[Expert@MyGW:0]#
```

### Example 3 - Resetting all debug flags in all debug modules

```
[Expert@MyGW:0]# fwaccel dbg resetall
Debug state was reset to default.
[Expert@MyGW:0]#
```

**Example 4 - Configuring debug filter for an SSH connection from 192.168.20.30 to 172.16.40.50**

```
[Expert@MyGW:0]# fwaccel dbg -f 192.168.20.30,*,172.16.40.50,22,6
Debug filter was set.
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dbg list

... ..

Debug filter: "<*,*,*,*,*>"
[Expert@MyGW:0]#
```

# fwaccel dos

## Description

The "fwaccel dos" (for IPv4) and "fwaccel6 dos" (for IPv6) commands control the Rate Limiting for DoS mitigation techniques in SecureXL on the local Security Gateway, or Cluster Member.

See [sk182350 - How to configure Rate Limiting rules for DoS Mitigation](#).

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- In the VSNext mode / Traditional VSX mode, you must go to the context of an applicable Virtual Gateway / Virtual System.
  - In Gaia Clish, run: `set virtual-system <VSID>`
  - In the Expert mode, run: `vsenv <VSID>`
- On Scalable Platforms (ElasticXL, Maestro, Scalable Chassis), you must run the required commands only in this way:
  - On the Security Group command line, only on the SMO Security Group Member.
  - In the Global Gaia Clish (`gclish`), must run these commands:
    - `fwaccel dos <Options>`
    - `fwaccel6 dos <Options>`
  - In the Expert mode, must run these commands (start with the "g\_" prefix):
    - `g_fwaccel dos <Options>`
    - `g_fwaccel6 dos <Options>`

## Command Line

| Platform                                                                                                          | Command to Run                                                                                     | Description of Command                                |

## Syntax for IPv4

```
fwaccel dos
  config <options>
  deny <options>
  drop_fragments <options>
  drop_opts <options>
  ioc_deny <options>
  ioc_deny_ext <options>
  ioc_monitor <options>
  ioc_monitor_ext <options>
  pbox <options>
  rate <options>
  stats <options>
```

## Syntax for IPv6

```
fwaccel6 dos
  config <options>
  deny <options>
  drop_frgs <options>
  drop_opts <options>
  ioc_deny <options>
  ioc_deny_ext <options>
  ioc_monitor <options>
  ioc_monitor_ext <options>
  pbox <options>
  rate <options>
  stats <options>
```

## Parameters

| Parameter                 | Description                                                                                                                                                         |

## fwaccel dos allow

### Description

The *fwaccel dos allow* command configures the allow-list for source IP addresses in the SecureXL Penalty Box.

This allow-list overrides which packet the SecureXL Penalty Box drops.

### Important:

- This command supports only IPv4.
- In the VSNext mode / Traditional VSX mode, you must go to the context of an applicable Virtual Gateway / Virtual System. In Gaia Clish, run: `set virtual-system <VSID>` In the Expert mode, run: `vsenv <VSID>`
- In a Cluster, you must configure all the Cluster Members in the same way.
- This allow-list overrides entries in the blacklist.  
Before you use a 3rd-party or automatic blacklists, add trusted networks and hosts to the allow-list to avoid outages.
- This allow-list unblocks IP Options and IP fragments from trusted sources when you explicitly configure one these SecureXL features:
  - `--enable-drop-opts`
  - `--enable-drop-frags`

See the ["fwaccel dos config" on page 1491](#) command.

### Notes:

- To allow-list the Rate Limiting policy, refer to the bypass action of the `fw samp` command.  
For example, `fw samp -a b ...`  
For more information about the `fw sam_policy` command, see the [R82.10 Performance Tuning Administration Guide](#) - Chapter *SecureXL Commands and Debug* - Section *fw sam\_policy*.
- This command is similar to the "fwaccel dos pbox allow" command (see ["fwaccel dos pbox" on page 1520](#)).
- Also, see the ["fwaccel synatk allow" on page 1614](#) command.

### Syntax for IPv4

```
fwaccel dos allow
  -a <IPv4 Address>[/<Subnet Prefix>]
  -d <IPv4 Address>[/<Subnet Prefix>]
  -F
  -l /<Path>/<Name of File>
  -L
  -s
```

## Parameters

| Parameter                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

### Example 1 - Adding a host IP address without optional subnet prefix

```
[Expert@MyGW:0]# fwaccel dos allow -a 192.168.20.40
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dos allow -s
192.168.20.40/32
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dos allow -F
[Expert@MyGW:0]# fwaccel dos allow -s
[Expert@MyGW:0]#
```

### Example 2 - Adding a host IP address with optional subnet prefix

```
[Expert@MyGW:0]# fwaccel dos allow -a 192.168.20.40/32
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dos allow -s
192.168.20.40/32
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dos allow -F
[Expert@MyGW:0]# fwaccel dos allow -s
[Expert@MyGW:0]#
```

### Example 3 - Adding a network IP address with mandatory subnet prefix

```
[Expert@MyGW:0]# fwaccel dos allow -a 192.168.20.0/24
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dos allow -s
192.168.20.0/24
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dos allow -F
[Expert@MyGW:0]# fwaccel dos allow -s
[Expert@MyGW:0]#
```

### Example 4 - Deleting an entry

```
[Expert@MyGW:0]# fwaccel dos allow -a 192.168.20.40/32
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dos allow -a 192.168.20.70/32
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dos allow -s
192.168.20.40/32
192.168.20.70/32
[Expert@MyGW:0]# fwaccel dos allow -d 192.168.20.70/32
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dos allow -s
192.168.20.40/32
[Expert@MyGW:0]#
```

## fwaccel dos config

### Description

The "fwaccel dos config" (for IPv4) and "fwaccel6 dos config" (for IPv6) commands show the global configuration parameters of the Rate Limiting for DoS mitigation in SecureXL.

These global parameters apply to all configured Rate Limiting rules.

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group. On Scalable Platforms (ElasticXL, Maestro, Scalable Chassis), you must run the required commands only in this way:
  - On the Security Group command line, only on the SMO Security Group Member.
  - In the Global Gaia Clish (gclish), must run these commands:
    - fwaccel dos <Options>
    - fwaccel6 dos <Options>
  - In the Expert mode, must run these commands (start with the "g\_" prefix):
    - g\_fwaccel dos <Options>
    - g\_fwaccel6 dos <Options>
- In the VSNext mode / Traditional VSX mode, you must go to the context of an applicable Virtual Gateway / Virtual System.
  - In Gaia Clish, run: set virtual-system <VSID>
  - In the Expert mode, run: vsenv <VSID>

### Syntax

```
{fwaccel | fwaccel6} dos config
  get
  set <options>
  reset-to-default
```

### Parameters and Options

| Parameter or Option | Description                          |
|---------------------|--------------------------------------|
| No Parameters       | Shows the applicable built-in usage. |
| get                 | Shows the configuration parameters.  |

| Parameter or Option              | Description                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>set &lt;options&gt;</code> | <p>This parameter is deprecated starting in R82.<br/>Use these commands:</p> <ul style="list-style-type: none"><li>▪ <a href="#">"fwaccel dos deny" on page 1496</a></li><li>▪ <a href="#">"fwaccel dos drop_fragments" on page 1504</a></li><li>▪ <a href="#">"fwaccel dos drop_opts" on page 1508</a></li><li>▪ <a href="#">"fwaccel dos pbox" on page 1520</a></li><li>▪ <a href="#">"fwaccel dos rate" on page 1528</a></li></ul> |
| <code>reset-to-default</code>    | <p>Resets the configuration parameters to their default values.</p> <p> <b>Note</b> - This command does not affect the rate limit rules, IP values in deny-lists or allow-lists.</p>                                                                                                                                                                 |

## Example

```
[Expert@MyGW>:0]# fwaccel dos config get
Rate Limit Rules:
    Status                                on (without policy)
    Internal Interfaces                    off
    Monitor-Only                           off
    Log Drops                              on
    Max Notifications Per-Second           100 logs/second
    Rule Cache                             on

Penalty Box:

## fwaccel dos deny

### Description

The "fwaccel dos deny" (for IPv4) and "fwaccel6 dos deny" (for IPv6) commands control the IP deny-list in SecureXL.

The deny-list blocks all traffic to and from the specified IP addresses.

The deny-list drops occur in SecureXL, which is more efficient than an Access Control Policy to drop the packets.

### Important:

- By default, the IP deny-list feature is enabled, without a Rate Limiting policy.
- By design, if you change the IP addresses in the Deny List with command line options and not through the corresponding files in the `$FWDIR/conf/deny_lists/` directory, then these changes do not survive a reboot.
- The Deny List scales up to millions of IP addresses.
- To enforce the IP deny-list in SecureXL, you must first enable the IP deny-lists. See these commands:
  - ["fwaccel dos config" on page 1491](#)
  - ["fw sam\\_policy" on page 1638](#) (configures more granular rules)
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group. On Scalable Platforms (ElasticXL, Maestro, Scalable Chassis), you must run the required commands only in this way:
  - On the Security Group command line, only on the SMO Security Group Member.
  - In the Global Gaia Clish (`gclish`), must run these commands:
    - `fwaccel dos <Options>`
    - `fwaccel6 dos <Options>`
  - In the Expert mode, must run these commands (start with the "g\_" prefix):
    - `g_fwaccel dos <Options>`
    - `g_fwaccel6 dos <Options>`
- In the VSNext mode / Traditional VSX mode, you must go to the context of an applicable Virtual Gateway / Virtual System.
  - In Gaia Clish, run: `set virtual-system <VSID>`
  - In the Expert mode, run: `vsenv <VSID>`

## Syntax

```
{fwaccel | fwaccel6} dos deny
    {-h | --help}
allow
    {-h | --help}
    {-a | --add} <IP Address>[/<Subnet Mask Length>]
    {-d | --delete} <IP Address>[/<Subnet Mask Length>]
    {-F | --flush}
    {-l | --load} /<Path>/<Name of File>
    {-s | --show}
{-a | --add} <IP Address>
{-c | --show-config}
{-d | --delete} <IP Address>
{-E | --set-enabled} {on | off}
{-F | --flush}
{-G | --set-log-drops} {on | off}
{-I | --set-enforce-internal} {on | off}
{-l | --load} /<Path>/<Name of File>
{-L | --load-default}
{-M | --set-monitor-only} {on | off}
{-N | --set-name} "<Name of IP Deny-list>"
{-O | --set-notif-rate} <Number>
{-R | --set-tcp-rst} {on | off}
{-s | --show}
```

## Parameters

| Parameter                              | Description                          |
|----------------------------------------|--------------------------------------|
| No Parameters                          | Shows the applicable built-in usage. |
| <code>-h</code><br><code>--help</code> | Shows the applicable built-in usage. |

| Parameter                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Example from a non-VSX Gateway

```
[Expert@MyGW:0]# fwaccel dos deny -c
Deny List:
      Status                               on (without policy)
      Internal Interfaces                  off
      Monitor-Only                        off
      Log Drops                           on
      Max Notifications Per-Second        100 logs/second
      Send TCP Reset                      off
      Name                                Deny List
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dos deny -s
The deny list is empty
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dos deny -a 1.1.1.1
Adding 1.1.1.1
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dos deny -s
1.1.1.1
[Expert@MyGW:0]# fwaccel dos deny -a 2.2.2.2
Adding 2.2.2.2
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dos deny -s
2.2.2.2
1.1.1.1
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dos deny -d 2.2.2.2
Deleting 2.2.2.2
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dos deny -s
1.1.1.1
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dos deny -F
All deny list entries deleted
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dos deny -s
The deny list is empty
[Expert@MyGW:0]#
```

## fwaccel dos drop\_fragments

### Description

The "fwaccel dos drop\_fragments" (for IPv4) and "fwaccel6 dos drop\_fragments" (for IPv6) commands control the drop of IP Fragments in SecureXL.

#### Important:

- By default, drops of IP Fragments are disabled.
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group. On Scalable Platforms (ElasticXL, Maestro, Scalable Chassis), you must run the required commands only in this way:
  - On the Security Group command line, only on the SMO Security Group Member.
  - In the Global Gaia Clish (gclish), must run these commands:
    - fwaccel dos <Options>
    - fwaccel6 dos <Options>
  - In the Expert mode, must run these commands (start with the "g\_" prefix):
    - g\_fwaccel dos <Options>
    - g\_fwaccel6 dos <Options>
- In the VSNext mode / Traditional VSX mode, you must go to the context of an applicable Virtual Gateway / Virtual System.
  - In Gaia Clish, run: set virtual-system <VSID>
  - In the Expert mode, run: vsenv <VSID>
- These commands survive a reboot.

### Syntax

```
{fwaccel | fwaccel6} dos drop_fragments
    {-h | --help}
allow
    {-h | --help}
    {-a | --add} <IP Address>[/<Subnet Mask Length>]
    {-d | --delete} <IP Address>[/<Subnet Mask Length>]
    {-F | --flush}
    {-l | --load} /<Path>/<Name of File>
    {-s | --show}
    {-c | --show-config}
    {-E | --set-enabled} {on | off}
    {-G | --set-log-drops} {on | off}
    {-I | --set-enforce-internal} {on | off}
    {-M | --set-monitor-only} {on | off}
    {-O | --set-notif-rate} <Number>}
```

## Parameters

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Parameter                                                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-O &lt;Number&gt;</code><br><code>--set-notif-rate &lt;Number&gt;</code> | <p>Configures the maximum number of logs per second for packet drops. When DoS / Rate Limiting blocks many packets, it can be important to limit the maximum number of the drop logs that the Security Gateway generates per second.</p> <p> <b>Notes:</b></p> <ul style="list-style-type: none"> <li>■ The default logging rate is 100 logs/second.</li> <li>■ This change survives a reboot.</li> </ul> |

### Example from a non-VSX Gateway

```
[Expert@MyGW:0]# fwaccel dos drop_fragments -c
Disallow IPv4 Fragments:
  Status                               off
  Internal Interfaces                  off
  Monitor-Only                        off
  Log Drops                           on
  Max Notifications Per-Second        100 logs/second
[Expert@MyGW:0]#
```

## fwaccel dos drop\_opts

### Description

The "fwaccel dos drop\_opts" (for IPv4) and "fwaccel6 dos drop\_opts" (for IPv6) commands control the drop of IP Options in SecureXL.

#### Important:

- By default, drops of IP Options are disabled.
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group. On Scalable Platforms (ElasticXL, Maestro, Scalable Chassis), you must run the required commands only in this way:
  - On the Security Group command line, only on the SMO Security Group Member.
  - In the Global Gaia Clish (gclish), must run these commands:
    - fwaccel dos <Options>
    - fwaccel6 dos <Options>
  - In the Expert mode, must run these commands (start with the "g\_" prefix):
    - g\_fwaccel dos <Options>
    - g\_fwaccel6 dos <Options>
- In the VSNext mode / Traditional VSX mode, you must go to the context of an applicable Virtual Gateway / Virtual System.
  - In Gaia Clish, run: set virtual-system <VSID>
  - In the Expert mode, run: vsenv <VSID>
- These commands survive a reboot.

### Syntax

```
{fwaccel | fwaccel6} dos drop_opts
    {-h | --help}
    allow
        {-h | --help}
        {-a | --add} <IP Address>[/<Subnet Mask Length>]
        {-d | --delete} <IP Address>[/<Subnet Mask Length>]
        {-F | --flush}
        {-l | --load} /<Path>/<Name of File>
        {-s | --show}
    {-c | --show-config}
    {-E | --set-enabled} {on | off}
    {-G | --set-log-drops} {on | off}
    {-I | --set-enforce-internal} {on | off}
    {-M | --set-monitor-only} {on | off}
    {-O | --set-notif-rate} <Number>}
```

## Parameters

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Parameter                                                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-O &lt;Number&gt;</code><br><code>--set-notif-rate &lt;Number&gt;</code> | <p>Configures the maximum number of logs per second for packet drops. When DoS / Rate Limiting blocks many packets, it can be important to limit the maximum number of the drop logs that the Security Gateway generates per second.</p> <p> <b>Notes:</b></p> <ul style="list-style-type: none"> <li>■ The default logging rate is 100 logs/second.</li> <li>■ This change survives a reboot.</li> </ul> |

### Example from a non-VSX Gateway

```
[Expert@MyGW:0]# fwaccel dos drop_opts -c
Disallow IP Options:
  Status                               off
  Internal Interfaces                  off
  Monitor-Only                        off
  Log Drops                           on
  Max Notifications Per-Second        100 logs/second
[Expert@MyGW:0]#
```

## fwaccel dos ioc\_deny

### Description

The "fwaccel dos ioc\_deny" (for IPv4) and "fwaccel6 dos ioc\_deny" (for IPv6) commands control the IP addresses that are blocked by Threat Prevention IoC Feeds based on feed files.

In addition, see:

- ["fwaccel dos ioc\\_deny\\_ext" on page 1514](#)
- ["fwaccel dos ioc\\_monitor" on page 1516](#)
- ["fwaccel dos ioc\\_monitor\\_ext" on page 1518](#)

### Important:

- The Security Gateway uses these commands to enforce Threat Prevention IoC Feeds.
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group. On Scalable Platforms (ElasticXL, Maestro, Scalable Chassis), you must run the required commands only in this way:
  - On the Security Group command line, only on the SMO Security Group Member.
  - In the Global Gaia Clish (gclish), must run these commands:
    - fwaccel dos <Options>
    - fwaccel6 dos <Options>
  - In the Expert mode, must run these commands (start with the "g\_" prefix):
    - g\_fwaccel dos <Options>
    - g\_fwaccel6 dos <Options>
- In the VSNext mode / Traditional VSX mode, you must go to the context of an applicable Virtual Gateway / Virtual System.
  - In Gaia Clish, run: `set virtual-system <VSID>`
  - In the Expert mode, run: `vsenv <VSID>`

### Syntax

```
}fwaccel |fwaccel6} dos ioc_deny
    {-h | --help}
    {-c | --show-config}
    {-F | --flush}
    {-G | --set-log-drops} {on | off}
    {-R | --set-tcp-rst} {on | off}
    {-s | --show}
```

## Parameters

| Parameter                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -h<br>--help                                | Shows the applicable built-in usage.                                                                                                                                                                                                                                                                                                                                                                         |
| -c<br>--show-config                         | Shows the current configuration.                                                                                                                                                                                                                                                                                                                                                                             |
| -F<br>--flush                               | Removes (flushes) all IP addresses from the IP deny-list.<br> <b>Important</b> - Do <b>not</b> run this command unless Check Point Support explicitly asked you to do so.                                                                                                                                                   |
| -G {on   off}<br>--set-log-drops {on   off} | Enables (on) or disables (off) the logging of packet drops.<br> <b>Notes:</b> <ul style="list-style-type: none"> <li>By default, the Security Gateway generates the "Drop" logs for traffic that the DoS / Rate Limiting feature blocked.</li> <li>By default, logging of packet drops is enabled.</li> </ul>               |
| -R {on   off}<br>--set-tcp-rst {on   off}   | Enables (on) or disables (off) the response with the TCP [RST] packet for TCP connections that the IP deny-list blocked.<br> <b>Notes:</b> <ul style="list-style-type: none"> <li>By default, SecureXL does not send the TCP [RST] packet for blocked TCP connections.</li> <li>This change survives a reboot.</li> </ul> |
| -s<br>--show                                | Shows the IP addresses in the IP deny-list.                                                                                                                                                                                                                                                                                                                                                                  |

## Example

```
[Expert@MyGW:0]# fwaccel dos ioc_deny -c
IOC deny list (from files):
  Status                               on (without policy)
  Internal Interfaces                  on
  Monitor-Only                        off
  Log Drops                           on
  Send TCP Reset                      off

[Expert@MyGW:0]#
```

## fwaccel dos ioc\_deny\_ext

### Description

The "fwaccel dos ioc\_deny\_ext" (for IPv4) and "fwaccel6 dos ioc\_deny\_ext" (for IPv6) commands control the IP addresses that are blocked by Threat Prevention IoC Feeds based on external feed files.

In addition, see:

- ["fwaccel dos ioc\\_deny" on page 1512](#)
- ["fwaccel dos ioc\\_monitor" on page 1516](#)
- ["fwaccel dos ioc\\_monitor\\_ext" on page 1518](#)

### Important:

- The Security Gateway uses these commands to enforce Threat Prevention IoC Feeds.
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group. On Scalable Platforms (ElasticXL, Maestro, Scalable Chassis), you must run the required commands only in this way:
  - On the Security Group command line, only on the SMO Security Group Member.
  - In the Global Gaia Clish (gclish), must run these commands:
    - fwaccel dos <Options>
    - fwaccel6 dos <Options>
  - In the Expert mode, must run these commands (start with the "g\_" prefix):
    - g\_fwaccel dos <Options>
    - g\_fwaccel6 dos <Options>
- In the VSNext mode / Traditional VSX mode, you must go to the context of an applicable Virtual Gateway / Virtual System.
  - In Gaia Clish, run: set virtual-system <VSID>
  - In the Expert mode, run: vsenv <VSID>

### Syntax

```
}fwaccel |fwaccel6} dos ioc_deny_ext
    {-h | --help}
    {-c | --show-config}
    {-F | --flush}
    {-G | --set-log-drops} {on | off}
    {-R | --set-tcp-rst} {on | off}
    {-s | --show}
```

## Parameters

| Parameter                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -h<br>--help                                | Shows the applicable built-in usage.                                                                                                                                                                                                                                                                                                                                                                         |
| -c<br>--show-config                         | Shows the current configuration.                                                                                                                                                                                                                                                                                                                                                                             |
| -F<br>--flush                               | Removes (flushes) all IP addresses from the IP deny-list.<br> <b>Important</b> - Do <b>not</b> run this command unless Check Point Support explicitly asked you to do so.                                                                                                                                                   |
| -G {on   off}<br>--set-log-drops {on   off} | Enables (on) or disables (off) the logging of packet drops.<br> <b>Notes:</b> <ul style="list-style-type: none"> <li>By default, the Security Gateway generates the "Drop" logs for traffic that the DoS / Rate Limiting feature blocked.</li> <li>By default, logging of packet drops is enabled.</li> </ul>               |
| -R {on   off}<br>--set-tcp-rst {on   off}   | Enables (on) or disables (off) the response with the TCP [RST] packet for TCP connections that the IP deny-list blocked.<br> <b>Notes:</b> <ul style="list-style-type: none"> <li>By default, SecureXL does not send the TCP [RST] packet for blocked TCP connections.</li> <li>This change survives a reboot.</li> </ul> |
| -s<br>--show                                | Shows the IP addresses in the IP deny-list.                                                                                                                                                                                                                                                                                                                                                                  |

## Example

```
[Expert@MyGW:0]# fwaccel dos ioc_deny_ext -c
IOC deny list (from external feeds):
  Status                               on (without policy)
  Internal Interfaces                  on
  Monitor-Only                        off
  Log Drops                           on
  Send TCP Reset                      off

[Expert@MyGW:0]#
```

## fwaccel dos ioc\_monitor

### Description

The "fwaccel dos ioc\_monitor" (for IPv4) and "fwaccel6 dos ioc\_monitor" (for IPv6) commands control the IP addresses that are monitored by Threat Prevention IoC Feeds based on feed files.

In addition, see:

- ["fwaccel dos ioc\\_deny" on page 1512](#)
- ["fwaccel dos ioc\\_deny\\_ext" on page 1514](#)
- ["fwaccel dos ioc\\_monitor\\_ext" on page 1518](#)

### Important:

- The Security Gateway uses these commands.
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group. On Scalable Platforms (ElasticXL, Maestro, Scalable Chassis), you must run the required commands only in this way:
  - On the Security Group command line, only on the SMO Security Group Member.
  - In the Global Gaia Clish (gclish), must run these commands:
    - fwaccel dos <Options>
    - fwaccel6 dos <Options>
  - In the Expert mode, must run these commands (start with the "g\_" prefix):
    - g\_fwaccel dos <Options>
    - g\_fwaccel6 dos <Options>
- In the VSNext mode / Traditional VSX mode, you must go to the context of an applicable Virtual Gateway / Virtual System.
  - In Gaia Clish, run: `set virtual-system <VSID>`
  - In the Expert mode, run: `vsenv <VSID>`

### Syntax

```
}fwaccel |fwaccel6} dos ioc_monitor
    {-h | --help}
    {-c | --show-config}
    {-F | --flush}
    {-G | --set-log-drops} {on | off}
    {-R | --set-tcp-rst} {on | off}
    {-s | --show}
```

## Parameters

| Parameter                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -h<br>--help                                | Shows the applicable built-in usage.                                                                                                                                                                                                                                                                                                                                                                         |
| -c<br>--show-config                         | Shows the current configuration.                                                                                                                                                                                                                                                                                                                                                                             |
| -F<br>--flush                               | Removes (flushes) all IP addresses from the IP deny-list.<br> <b>Important</b> - Do <b>not</b> run this command unless Check Point Support explicitly asked you to do so.                                                                                                                                                   |
| -G {on   off}<br>--set-log-drops {on   off} | Enables (on) or disables (off) the logging of packet drops.<br> <b>Notes:</b> <ul style="list-style-type: none"> <li>By default, the Security Gateway generates the "Drop" logs for traffic that the DoS / Rate Limiting feature blocked.</li> <li>By default, logging of packet drops is enabled.</li> </ul>               |
| -R {on   off}<br>--set-tcp-rst {on   off}   | Enables (on) or disables (off) the response with the TCP [RST] packet for TCP connections that the IP deny-list blocked.<br> <b>Notes:</b> <ul style="list-style-type: none"> <li>By default, SecureXL does not send the TCP [RST] packet for blocked TCP connections.</li> <li>This change survives a reboot.</li> </ul> |
| -s<br>--show                                | Shows the IP addresses in the IP deny-list.                                                                                                                                                                                                                                                                                                                                                                  |

## Example

```
[Expert@MyGW:0]# fwaccel dos ioc_monitor -c
IOC monitor-only list (from files):
  Status                               on (without policy)
  Internal Interfaces                  on
  Monitor-Only                        on
  Log Drops                           on
  Send TCP Reset                       off

[Expert@MyGW:0]#
```

## fwaccel dos ioc\_monitor\_ext

### Description

The "fwaccel dos ioc\_monitor\_ext" (for IPv4) and "fwaccel6 dos ioc\_monitor\_ext" (for IPv6) commands control the IP addresses that are monitored by Threat Prevention external IoC Feeds.

In addition, see:

- ["fwaccel dos ioc\\_deny" on page 1512](#)
- ["fwaccel dos ioc\\_deny\\_ext" on page 1514](#)
- ["fwaccel dos ioc\\_monitor" on page 1516](#)

### Important:

- The Security Gateway uses these commands.
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group. On Scalable Platforms (ElasticXL, Maestro, Scalable Chassis), you must run the required commands only in this way:
  - On the Security Group command line, only on the SMO Security Group Member.
  - In the Global Gaia Clish (gclish), must run these commands:
    - fwaccel dos <Options>
    - fwaccel6 dos <Options>
  - In the Expert mode, must run these commands (start with the "g\_" prefix):
    - g\_fwaccel dos <Options>
    - g\_fwaccel6 dos <Options>
- In the VSNext mode / Traditional VSX mode, you must go to the context of an applicable Virtual Gateway / Virtual System.
  - In Gaia Clish, run: `set virtual-system <VSID>`
  - In the Expert mode, run: `vsenv <VSID>`

### Syntax

```
}fwaccel |fwaccel6} dos ioc_monitor_ext
    {-h | --help}
    {-c | --show-config}
    {-F | --flush}
    {-G | --set-log-drops} {on | off}
    {-R | --set-tcp-rst} {on | off}
    {-s | --show}
```

## Parameters

| -F<br>--flush                               | Removes (flushes) all IP addresses from the IP deny-list.<br> <b>Important</b> - Do <b>not</b> run this command unless Check Point Support explicitly asked you to do so.                                                                                                                                                   |
| -G {on   off}<br>--set-log-drops {on   off} | Enables (on) or disables (off) the logging of packet drops.<br> <b>Notes:</b> <ul style="list-style-type: none"> <li>By default, the Security Gateway generates the "Drop" logs for traffic that the DoS / Rate Limiting feature blocked.</li> <li>By default, logging of packet drops is enabled.</li> </ul>               |
| -R {on   off}<br>--set-tcp-rst {on   off}   | Enables (on) or disables (off) the response with the TCP [RST] packet for TCP connections that the IP deny-list blocked.<br> <b>Notes:</b> <ul style="list-style-type: none"> <li>By default, SecureXL does not send the TCP [RST] packet for blocked TCP connections.</li> <li>This change survives a reboot.</li> </ul> |
| -s<br>--show                                | Shows the IP addresses in the IP deny-list.                                                                                                                                                                                                                                                                                                                                                                  |

## Example

```
[Expert@MyGW:0]# fwaccel dos ioc_monitor_ext -c
IOC monitor-only list (from files):
  Status                               on (without policy)
  Internal Interfaces                  on
  Monitor-Only                        on
  Log Drops                           on
  Send TCP Reset                       off

[Expert@MyGW:0]#
```

## fwaccel dos pbox

### Description

The "fwaccel dos pbox" (for IPv4) and "fwaccel6 dos pbox" (for IPv6) commands control the Penalty Box deny-list in SecureXL.

The SecureXL Penalty Box is a mechanism that performs an early drop of packets that arrive from suspected sources. The purpose of this feature is to allow the Security Gateway to cope better under high traffic load, possibly caused by a DoS/DDoS attack.

The SecureXL Penalty Box detects clients that send packets, which the Access Control Policy drops, and clients that violate the IPS protections. If the SecureXL Penalty Box detects a specific client frequently, it puts that client in a penalty box. From that point, SecureXL drops all packets that arrive from the blocked source IP address.

The Penalty Box allow-list in SecureXL configures the source IP addresses, which the SecureXL Penalty Box never blocks.

### Important:

- By default, the Penalty Box is disabled.
- To enforce the Penalty Box in SecureXL, you must first enable the Penalty Box. See:
  - ["fwaccel dos config" on page 1491](#)
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group. On Scalable Platforms (ElasticXL, Maestro, Scalable Chassis), you must run the required commands only in this way:
  - On the Security Group command line, only on the SMO Security Group Member.
  - In the Global Gaia Clish (gclish), must run these commands:
    - `fwaccel dos <Options>`
    - `fwaccel6 dos <Options>`
  - In the Expert mode, must run these commands (start with the "g\_" prefix):
    - `g_fwaccel dos <Options>`
    - `g_fwaccel6 dos <Options>`
- In the VSNext mode / Traditional VSX mode, you must go to the context of an applicable Virtual Gateway / Virtual System.
  - In Gaia Clish, run: `set virtual-system <VSID>`
  - In the Expert mode, run: `vsenv <VSID>`
- In a Scalable Platform, when you add a new Security Group Member to a Security Group, the new Security Group Member pulls these configuration files:
  - `$FWDIR/conf/pbox-whitelist-v4.conf`
  - `$FWDIR/conf/pbox-whitelist-v6.conf`

## Syntax

```
{fwaccel | fwaccel6} dos pbox
    {-h | --help}
    allow
        {-h | --help}
        {-a | --add} <IP Address>[/<Subnet Mask>]
        {-d | --delete} <IP Address>[/<Subnet Mask>]
        {-F | --flush}
        {-l | --load} /<Path>/<Name of File>
        {-s | --show}
    {-c | --show-config}
    {-E | --set-enabled} {on | off}
    {-F | --flush}
    {-G | --set-log-drops} {on | off}
    {-I | --set-enforce-internal} {on | off}
    {-L | --set-log-reported} {on | off}
    {-M | --set-monitor-only} {on | off}
    {-O | --set-notif-rate} <Number>}
    {-P | --set-drops-threshold} <Number>}
    {-R | --set-tcp-rst} {on | off}
    {-s | --show}
    {-T | --set-timeout} <Number>}
```

## Parameters

| Parameter     | Description                          |
|---------------|--------------------------------------|
| No Parameters | Shows the applicable built-in usage. |
| -h<br>--help} | Shows the applicable built-in usage. |

| Parameter                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <code>-s</code><br><code>--show</code>                                      | Shows the IP addresses in the IP deny-list.                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>-T &lt;Number&gt;</code><br><code>--set-timeout &lt;Number&gt;</code> | <p>Configures the timeout (in seconds) for blocked IP addresses in the Penalty Box.</p> <p>After this timeout reaches 0, SecureXL removes the blocked IP address from the Penalty Box.</p> <p> <b>Notes:</b></p> <ul style="list-style-type: none"> <li>■ The default timeout is 180 seconds.</li> <li>■ This change survives a reboot.</li> </ul> |

## Example 1 - Default Configuration

```
[Expert@MyGW:0]# fwaccel dos pbox -c
Penalty Box:
  Status                      off
  Internal Interfaces         off
  Monitor-Only                off
  Log Drops                   on
  Max Notifications Per-Second 100 logs/second
  Send TCP Reset              off
  Timeout for Blocked IPs      180 seconds
  Has Blocked IPs             no
  Log when a new IP is blocked on
  Drop rate to trigger on      500 packets/second
[Expert@MyGW:0]#
```

## Example 2 - Adding a host IP address without the optional subnet mask length

```
[Expert@MyGW:0]# fwaccel dos pbox allow -a 192.168.20.40
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dos pbox allow -s
192.168.20.40/32
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dos pbox allow -F
[Expert@MyGW:0]# fwaccel dos pbox allow -s
[Expert@MyGW:0]#
```

### Example 3 - Adding a host IP address with the optional subnet mask length

```
[Expert@MyGW:0]# fwaccel dos pbox allow -a 192.168.20.40/32
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dos pbox allow -s
192.168.20.40/32
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dos pbox allow -F
[Expert@MyGW:0]# fwaccel dos pbox allow -s
[Expert@MyGW:0]#
```

### Example 4 - Adding a network IP address with the mandatory subnet mask length

```
[Expert@MyGW:0]# fwaccel dos pbox allow -a 192.168.20.0/24
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dos pbox allow -s
192.168.20.0/24
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dos pbox allow -F
[Expert@MyGW:0]# fwaccel dos pbox allow -s
[Expert@MyGW:0]#
```

### Example 5 - Deleting a host entry

```
[Expert@MyGW:0]# fwaccel dos pbox allow -a 192.168.20.40/32
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dos pbox allow -a 192.168.20.70/32
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dos pbox allow -s
192.168.20.40/32
192.168.20.70/32
[Expert@MyGW:0]# fwaccel dos pbox allow -d 192.168.20.70/32
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dos pbox allow -s
192.168.20.40/32
[Expert@MyGW:0]#
```

## fwaccel dos rate

### Description

The "fwaccel dos rate" (for IPv4) and "fwaccel6 dos rate" (for IPv6) commands show and install the Rate Limiting policy in SecureXL.

#### Important:

- By default, the Rate Limiting policy feature is enabled without any rules.
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group. On Scalable Platforms (ElasticXL, Maestro, Scalable Chassis), you must run the required commands only in this way:
  - On the Security Group command line, only on the SMO Security Group Member.
  - In the Global Gaia Clish (`gclish`), must run these commands:
    - `fwaccel dos <Options>`
    - `fwaccel6 dos <Options>`
  - In the Expert mode, must run these commands (start with the "g\_" prefix):
    - `g_fwaccel dos <Options>`
    - `g_fwaccel6 dos <Options>`
- In the VSNext mode / Traditional VSX mode, you must go to the context of an applicable Virtual Gateway / Virtual System.
  - In Gaia Clish, run: `set virtual-system <VSID>`
  - In the Expert mode, run: `vsenv <VSID>`

### Notes

- If you install a new rate limiting policy with more than one rule, it automatically enables the rate limiting feature.

To disable the rate limiting feature manually, run this command (see ["fwaccel dos config" on page 1491](#)):

```
{fwaccel | fwaccel6} dos config set --disable-rate-limit
```

- To delete the current rate limiting policy, install a new policy with zero rules.

## Syntax

```
{fwaccel | fwaccel6} dos rate {-h | --help}
```

```
{fwaccel | fwaccel6} dos rate
    add --help
    add [<SIC Connection>] <Options> <Match Conditions> <Limit>
    <Tracking>
    add batch /<Path>/<Name of File>
```

```
{fwaccel | fwaccel6} dos rate
    counters --help
    counters
    counters '<Rule Index>'
    counters '<Rule UID>'
```

```
{fwaccel | fwaccel6} dos rate
    del --help
    del all
    del '<Rule UID>'
    del batch /<Path>/<Name of File>
```

```
{fwaccel | fwaccel6} dos rate
    get --help
    get {-r | -l | -o /<Path>/<Name of File>}
    get [-n] -u '<Rule UID>'
    get [-n] -k <Search Key>
    get [-n] -v <Search Value>
    get --show-tab
    get --show-counters
```

```
{fwaccel | fwaccel6} dos rate
    {-c | --show-config}
    {-E | --set-enabled} {on | off}
    {-G | --set-log-drops} {on | off}
    {-I | --set-enforce-internal} {on | off}
    {-M | --set-monitor-only} {on | off}
    {-O | --set-notif-rate} <Number>
    {-R | --set-rule-cache} {on | off}
```

## Parameters

| Parameter                                                                                                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Adding an IPv4 rule to the Rate Limiting policy

### Explanation

#### Syntax

```
{fwaccel | fwaccel6} dos rate add [<SIC Connection>] <Options>
<Match Conditions> <Limit> <Tracking>
```

#### Parameters

## <SIC Connection>

You can use this optional parameter only when running the command from the Management Server's command-line to configure DoS / Rate Limiting policy rules on a Security Gateway / each Cluster Member.

Use one of these:

- `-S <IP Address of Management Interface>`

Specifies the IP address of the management interface (default=localhost) on a Security Gateway / Cluster Member.

Example:

```
fwaccel dos rate add -S 192.168.1.101 source any pkt-rate 100000
```

- `-s <SIC Name>`

Specifies the SIC Name of a VSNext Virtual Gateway / Traditional VSX Gateway / Traditional VSX Cluster Member.

Example:

```
fwaccel dos rate add -S 192.168.1.101 -s my_virtual_system_1 source any pkt-rate 100000
```

## <Options>

These parameters affect the general behavior of a given policy rule.

 **Important** - If you would like to use these options, you must specify them in the CLI syntax in front of the "*<Match Conditions>*" or the "*<Limit>*".

| Parameter                       | Description                                                                                                                                                                             |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-t &lt;Timeout&gt;</code> | <p>Automatically deletes the rule after the specified number of seconds.</p> <p>Default value: None</p> <p>Example:</p> <pre>fwaccel dos rate add -t 2 source any pkt-rate 100000</pre> |

| Parameter                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-a {d   n   b}</code>         | <p>Specifies the action.<br/>One of these:</p> <ul style="list-style-type: none"> <li>■ <code>-a d</code><br/><code>-action drop</code><br/>Drop all packets that violate this rule (this is the default).</li> <li>■ <code>-a n</code><br/><code>-action notify</code><br/>Notify, but do not drop packets that violate this rule (meaning, Monitor-only mode).</li> <li>■ <code>-a b</code><br/><code>-action bypass</code><br/>Bypass DoS / Rate Limiting policy for all packets that match this rule (meaning, Allow List).<br/>Limits and the "track" option are not relevant for bypass rules and should not be specified.</li> </ul> <p>Example:<br/> <pre>fwaccel dos rate add -a b source cidr:192.168.0.0/16</pre> </p> |
| <code>-l {r   a}</code>             | <p>Specifies the Security Gateway log type:</p> <ul style="list-style-type: none"> <li>■ <code>-l r</code><br/><code>-log regular</code><br/>Regular log (this is the default).</li> <li>■ <code>-l a</code><br/><code>-log alert</code><br/>Alert.</li> </ul> <p>Example:<br/> <pre>fwaccel dos rate add -l a source any pkt-rate 100000</pre> </p>                                                                                                                                                                                                                                                                                                                                                                              |
| <code>-n '&lt;Rule Name&gt;'</code> | <p>Specifies the rule name.</p> <p> <b>Important</b> - The quote marks (single or double) are mandatory.</p> <p>Example:<br/> <pre>fwaccel dos rate add -n "This is a Rule Name" source any pkt-rate 100000</pre> </p>                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Parameter                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-c</code><br><code>'&lt;Comment&gt;'</code>    | <p>Specifies the rule comment.</p> <p> <b>Important</b> - The quote marks (single or double) are mandatory.</p> <p>Example:</p> <pre>fwaccel dos rate add -c "This is a Comment" source any pkt-rate 100000</pre>                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>-o</code><br><code>'&lt;Originator&gt;'</code> | <p>Specifies the rule originator.</p> <p> <b>Important</b> - The quote marks (single or double) are mandatory.</p> <p>Example:</p> <pre>fwaccel dos rate add -o "John Doe" source any pkt-rate 100000</pre>                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>-f &lt;Security Gateway&gt;</code>             | <p>Specifies the Security Gateway on which to enforce this rule. Typically this option is only used when administrating rules remotely.</p> <p>Valid values are:</p> <ul style="list-style-type: none"> <li>■ <code>"all"</code><br/>Enforce this rule on all Security Gateways (this is the default).</li> <li>■ <code>&lt;Name of Security Gateway Object&gt;</code><br/>Enforce this rule on the specified Security Gateway.</li> <li>■ <code>&lt;Name of Network Group Object&gt;</code><br/>Enforce this rule on all Security Gateways listed in the specified Network Group object.</li> </ul> <p>Example:</p> <pre>fwaccel dos rate add -S 192.168.1.101 -f test_ gateway_1 source any pkt-rate 100000</pre> |

### <Match Conditions>

Rate limiting policy rules can specify 3 different types of match conditions:

- Source IP address
- Destination IP address
- IP protocol, or IP Protocol + destination port

If a type of match condition is not specified, it defaults to "any", but at least one source or destination match condition must be included in the rule.

If a source match condition or a destination match condition does not have a format specified, it defaults to "cidr:" or "range:".

Multiple match conditions can be combined to match specific network traffic.

The 3 different types of match conditions are described below:

- Source Match Condition
- Destination Match Condition
- Service Match Condition

### Source Match Condition

The source match conditions are used to specify which source IP addresses match the rule.

The default value is "any".

| Source                   | Description                                                                                                                                                                                                                             |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| any                      | Any/all source IP addresses match this DoS / Rate Limiting rule.<br>This is the default if no source match condition is specified.<br>Example:<br>fwaccel dos rate add source any pkt-rate 100000                                       |
| range:<MIN> [-<MAX>]     | Specifies a range of IP addresses.<br>If <MAX> is not specified, then the range represents a single IP address.<br>Example:<br>fwaccel dos rate add source range:10.0.0.1-10.0.0.254 pkt-rate 100000                                    |
| cidr:<ADDRESS> [/<MASK>] | Specifies a network using the CIDR notation.<br>If the mask parameter is not provided, then the expression represents a specific host address.<br>Example:<br>fwaccel dos rate add source cidr:10.0.0.0/24 service 6/22 pkt-rate 100000 |

| Source                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>cc:&lt;COUNTRY_CODE&gt;</code>              | <p><b>Note</b> - This parameter is not supported (Known Limitation PMTR-87460).</p> <p>Two-letter code defined in ISO 3166-1 alpha-2.</p> <p>The rule matches the country code to the IP addresses assigned to this country, based on the Geo IP database.</p> <p><b>Example:</b></p> <pre>fwaccel dos rate add source cc:US pkt-rate 100000</pre>                                                                                |
| <code>asn:&lt;AUTONOMOUS_SYSTEM_NUMBER&gt;</code> | <p><b>Note</b> - This parameter is not supported (Known Limitation PMTR-87460).</p> <p>Valid value syntax is ASnnnn, where nnnn is a number unique to the specific organization.</p> <p>The rule matches the AS number of the organization to the IP addresses that are assigned to this organization, based on the Geo IP database.</p> <p><b>Example:</b></p> <pre>fwaccel dos rate add source asn:AS1234 pkt-rate 100000</pre> |
| <code>source-negated {true   false}</code>        | <p>If not specified, the default is "false".</p> <p>When set to "true", it inverts the match condition such that the rule matches all source IP addresses except for the given value.</p> <p><b>Example:</b></p> <pre>fwaccel dos rate add source-negated true source cidr:10.0.0.0/8 pkt-rate 100000</pre>                                                                                                                       |

### Destination Match Condition

The destination match conditions are used to specify which destination IP addresses match the rule.

The default value is "any".

| Destination                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| any                            | <p>Any/all source IP addresses match this DoS / Rate Limiting rule.</p> <p>This is the default if no source match condition is specified.</p> <p>Example:</p> <pre>fwaccel dos rate add destination any pkt-rate 100000</pre>                                                                                                                                                                                                   |
| range:<MIN><br>[-<MAX>]        | <p>Specifies a range of IP addresses.</p> <p>If &lt;MAX&gt; is not specified, then the range represents a single IP address.</p> <p>Example:</p> <pre>fwaccel dos rate add destination range:10.0.0.1-10.0.0.254 pkt-rate 100000</pre>                                                                                                                                                                                          |
| cidr:<ADDRESS><br>[/<MASK>]    | <p>Specifies a network using the CIDR notation.</p> <p>If the mask parameter is not provided, then the expression represents a specific host address.</p> <p>Example:</p> <pre>fwaccel dos rate add destination cidr:10.0.0.0/24 service 6/22 pkt-rate 100000</pre>                                                                                                                                                             |
| cc:<COUNTRY_CODE>              | <p><b>Note</b> - This parameter is not supported (Known Limitation PMTR-87460).</p> <p>Two-letter code defined in ISO 3166-1 alpha-2.</p> <p>The rule matches the country code to the IP addresses assigned to this country, based on the Geo IP database.</p> <p>Example:</p> <pre>fwaccel dos rate add destination cc:US pkt-rate 100000</pre>                                                                                |
| asn:<AUTONOMOUS_SYSTEM_NUMBER> | <p><b>Note</b> - This parameter is not supported (Known Limitation PMTR-87460).</p> <p>Valid value syntax is ASnnnn, where nnnn is a number unique to the specific organization.</p> <p>The rule matches the AS number of the organization to the IP addresses that are assigned to this organization, based on the Geo IP database.</p> <p>Example:</p> <pre>fwaccel dos rate add destination asn:AS1234 pkt-rate 100000</pre> |

| Destination                      | Description                                                                                                                                                                                                                                                                                                    |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| source-negated<br>{true   false} | <p>If not specified, the default is "false".</p> <p>When set to "true", it inverts the match condition such that the rule matches all source IP addresses except for the given value.</p> <p>Example:</p> <pre>fwaccel dos rate add destination-negated true destination cidr:10.0.0.0/8 pkt-rate 100000</pre> |

## Service Match Condition

The service match conditions are used to specify which network services (meaning, <ipproto>:<port>) match the rule.

The default value is any protocol, any port.

| Service                 | Description                                                                                                                                                                                                                                                                                         |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| any                     | <p>All IP protocols and ports match this DoS / Rate Limiting rule. This is the default if no service match condition is specified.</p> <p>Example:</p> <pre>fwaccel dos rate add source cidr:10.0.0.0/8 service any pkt-rate 100000</pre>                                                           |
| <PROTO>                 | <p>IANA IP Protocol number. See <a href="#">IANA Protocol Numbers</a>. For example, "6" for TCP.</p> <p>Causes this rule to apply only to the given protocol . Valid values are 1 through 255.</p> <p>Example:</p> <pre>fwaccel dos rate add source cidr:10.0.0.0/8 service 1 pkt-rate 100000</pre> |
| <MIN_PROTO>-<MAX_PROTO> | <p>For example, "1-6" would specify all IP protocols with numbers between 1 and 6.</p> <p>Causes this rule to match all protocol numbers within the given range.</p> <p>Example:</p> <pre>fwaccel dos rate add source cidr:10.0.0.0/8 service 1-6 pkt-rate 100000</pre>                             |

| Service                                                      | Description                                                                                                                                                                                                                                                                                                       |
|--------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;PROTO&gt;/&lt;PORT&gt;</code>                      | <p>Only valid for the TCP and UDP protocols.</p> <p>Causes the rule to match the specific IP protocol and destination port number.</p> <p>Example:</p> <pre>fwaccel dos rate add source cidr:10.0.0.0/8 service 6/22 pkt-rate 100000</pre>                                                                        |
| <code>&lt;PROTO&gt;/&lt;MIN_PORT&gt;-&lt;MAX_PORT&gt;</code> | <p>Only valid for the TCP and UDP protocols.</p> <p>Causes the rule to match the specific IP protocol, and range of destination port numbers.</p> <p>Example:</p> <pre>fwaccel dos rate add source cidr:10.0.0.0/8 service 6/0-1024 pkt-rate 100000</pre>                                                         |
| <code>service-negated {true   false}</code>                  | <p>If not specified, the default is "false".</p> <p>When set to "true", it inverts the match condition such that the rule matches all services/ports except for the given value.</p> <p>Example:</p> <pre>fwaccel dos rate add source cidr:10.0.0.0/8 service-negated true service 6/0-1024 pkt-rate 100000</pre> |

**<Limit>**

The limit defines the trigger threshold for a policy rule (for example, maximum allowable packets-per-second).

Only a single limit is allowed for each rule.

| Limit                         | Description                                                                                                                                                                                |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>concurrent-conns</code> | <p>Maximum number of simultaneously active connections allowed by this rule.</p> <p>Example:</p> <pre>fwaccel dos rate add source cidr:10.0.0.0/8 service 6/22 concurrent-conns 5000</pre> |

| Limit                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| concurrent-conns-ratio | <p>Limit the maximum number of connections to a percentage of the total number of active connections passing through the Security Gateway.</p> <p>The value is expressed as a ratio in parts-per-65536.</p> <p>For example, a value of 6553, would allow a ratio of about 10%.</p> <p> <b>Note</b> - To prevent false positives, a global minimum of 1000 connections must be simultaneously active (within the specific Security Gateway) before this limit will activate.</p> <p>Example:</p> <pre>fwaccel dos rate add source cidr:10.0.0.0/8 service 6/22 concurrent-conns-ratio 6553</pre> |
| new-conn-rate          | <p>Maximum number of connections-per-second allowed by this rule.</p> <p>The minimum value is 1.</p> <p>Example:</p> <pre>fwaccel dos rate add source cidr:10.0.0.0/8 service 6/22 new-conn-rate 100</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| new-conn-rate-ratio    | <p>Limit the maximum connections-per-second to a percentage of the total connections-per-second passing through the Security Gateway.</p> <p>The value is expressed as a ratio in parts-per-65536.</p> <p>For example, a value of 6553, would allow a ratio of about 10%.</p> <p> <b>Note</b> - To prevent false positives, a global minimum of 100 new connections-per-second must flow through the Security Gateway before this limit will activate.</p> <p>Example:</p> <pre>fwaccel dos rate add source cidr:10.0.0.0/8 service 6/22 new-conn-rate-ratio 6553</pre>                       |
| pkt-rate               | <p>Maximum number of packets-per-second allowed by this rule.</p> <p>A value of zero will block all traffic that matches this rule.</p> <p>Example:</p> <pre>fwaccel dos rate add source cidr:10.0.0.0/8 service 6/22 pkt-rate 5000</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Limit           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pkt-rate-ratio  | <p>Limit the maximum packets-per-second to a percentage of the total packets-per-second passing through the Security Gateway. The value is expressed as a ratio in parts-per-65536. For example, a value of 6553, would allow a ratio of about 10%.</p> <p> <b>Note</b> - To prevent false positives, a global minimum of 1000 packets-per-second must flow through the Security Gateway before this limit will activate.</p> <p>Example:</p> <pre>fwaccel dos rate add source cidr:10.0.0.0/8 service 6/22 pkt-rate-ratio 6553</pre> |
| byte-rate       | <p>Maximum number of bytes-per-second allowed by this rule. A value of zero will block all traffic that matches this rule.</p> <p>Example:</p> <pre>fwaccel dos rate add source cidr:10.0.0.0/8 service 6/22 byte-rate 500000</pre>                                                                                                                                                                                                                                                                                                                                                                                    |
| byte-rate-ratio | <p>Limit the maximum bytes-per-second to a percentage of the total bytes-per-second passing through the Security Gateway. The value is expressed as a ratio in parts-per-65536. For example, a value of 6553, would allow a ratio of about 10%.</p> <p> <b>Note</b> - To prevent false positives, a global minimum of 100000 bytes-per-second must flow through the Security Gateway before this limit will activate.</p> <p>Example:</p> <pre>fwaccel dos rate add source cidr:10.0.0.0/8 service 6/22 byte-rate-ratio 6553</pre>  |

### <Tracking>

The tracking mode controls how the limits are applied to traffic that matches the rule.

| Tracking Mode         | Description                                                                                                                                                                       |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Default (no tracking) | <p>The all traffic matching the rule is blocked if the rule is violated</p> <p>Example:</p> <pre>fwaccel dos rate add source cidr:10.0.0.0/8 service 6/22 new-conn-rate 100</pre> |

| Tracking Mode       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| source              | <p>Each source IP address is tracked separately.</p> <p>If traffic from a given source IP address violates this rule, only that source IP address is blocked.</p> <p>Also, one source IP will not affect the rate limit counters of another source IP.</p> <p>Example:</p> <pre>fwaccel dos rate add source cidr:10.0.0.0/8 service 6/22 new-conn-rate 100 track source</pre>                                                                                   |
| source-service      | <p>Each source IP address plus service is tracked separately.</p> <p>If traffic from a given source IP and service violates this rule, only that specific service and source IP are blocked.</p> <p>Other services from the same source IP are unaffected by the rule (unless they violate the rule also).</p> <p>Example:</p> <pre>fwaccel dos rate add source cidr:10.0.0.0/8 service 6/22 new-conn-rate 100 track source- service</pre>                      |
| destination         | <p>Each destination IP address is tracked separately.</p> <p>If traffic to a given destination IP address violates this rule, only that destination IP address is blocked.</p> <p>Also, one destination IP will not affect the rate limit counters of another destination IP.</p> <p>Example:</p> <pre>fwaccel dos rate add source cidr:10.0.0.0/8 service 6/22 new-conn-rate 100 track destination</pre>                                                       |
| destination-service | <p>Each destination IP address plus service is tracked separately.</p> <p>If traffic to a given destination IP and service violates this rule, only that specific service and destination IP are blocked.</p> <p>Other services for the same destination IP are unaffected by the rule (unless they violate the rule also).</p> <p>Example:</p> <pre>fwaccel dos rate add source cidr:10.0.0.0/8 service 6/22 new-conn-rate 100 track destination-service</pre> |

## Adding IPv4 rules in a batch mode to the Rate Limiting policy

### Procedure

1. Add the list of rules to a plain-text file (one rule on each line).

Remove the "fwaccel dos rate add" command prefix from each rule.

Example:

```
service any source cidr:192.168.2.0/24 pkt-rate 1000
service any source cidr:192.168.2.17 concurrent-conns 150
```

2. Use the batch command to load the file:

```
{fwaccel | fwaccel6} dos rate add batch /<Path>/<Name of File>
```

Example:

```
fwaccel dos rate add batch /var/log/rule_config.txt
```

## Viewing information about the rules the Rate Limiting policy

### Explanation

Syntax:

```
{fwaccel | fwaccel6} dos rate
  get --help
  get {-r | -l | -o /<Path>/<Name of File>}
  get [-n] -u '<Rule UID>'
  get [-n] -k <Search Key>
  get [-n] -v <Search Value>
  get --show-tab
  get --show-counters
```

Parameters:

| Parameter | Description                          |
|-----------|--------------------------------------|
| --help}   | Shows the applicable built-in usage. |

| Parameter                           | Description                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -r                                  | <p>Shows parameters of each rule in the legacy form - each entire rule on a separate line.</p> <p>This is the default output format.</p> <p>Example:</p> <pre>operation=add uid=&lt;66b101e7,00000000,cd18e2cd,000019bf&gt; target=all timeout=none action=drop log=regular source=cidr:192.168.17.2 service=6/22 concurrent- conns=5</pre>           |
| -l                                  | <p>Shows parameters of each rule on separate lines.</p> <p>Example:</p> <pre>uid &lt;66b101e7,00000000,cd18e2cd,000019bf&gt; target all timeout 2147483647 action drop log regular source cidr:192.168.17.2 service 6/22 concurrent-conns 5</pre>                                                                                                     |
| -o<br>/<Path>/<<br>Name of<br>File> | <p>Saves the output in the specified file.</p> <p>Format of the rules will be similar to what is expected to add rules in the Batch Mode.</p>                                                                                                                                                                                                         |
| -n                                  | Negates the search expression.                                                                                                                                                                                                                                                                                                                        |
| -u '<Rule<br>UID>'                  | <p>Specifies the Rule UID to show only a specific rule.</p> <p> <b>Important</b> - The quote marks (single or double) and angle brackets ('&lt;...&gt;') are mandatory.</p> <p>To see the UID for each rule, run:</p> <pre>{fwaccel   fwaccel6} dos rate get</pre> |

| Parameter                            | Description                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-k &lt;Search Key&gt;</code>   | <p>The search key.<br/>One of these:</p> <ul style="list-style-type: none"> <li>■ source</li> <li>■ destination</li> <li>■ service</li> <li>■ concurrent-conns</li> <li>■ concurrent-conns-ratio</li> <li>■ pkt-rate</li> <li>■ pkt-rate-ratio</li> <li>■ byte-rate</li> <li>■ byte-rate-ratio</li> <li>■ new-conn-rate</li> <li>■ new-conn-rate-ratio</li> </ul> |
| <code>-v &lt;Search Value&gt;</code> | Specifies the search value.                                                                                                                                                                                                                                                                                                                                       |
| <code>--show-tab</code>              | Also shows the output of the "fwaccel tab" command. See <a href="#">"fwaccel tab" on page 1629</a> .                                                                                                                                                                                                                                                              |
| <code>--show-counters</code>         | Also shows the output of the "fwaccel dos rate counters" command.                                                                                                                                                                                                                                                                                                 |

#### Examples:

- Show all DoS / Rate Limiting rules:

```
[Expert@MyGW:0]# fwaccel dos rate get
fwaccel dos rate add -i
'<66b101e7,00000000,cd18e2cd,000019bf>' -action drop -log
regular source cidr:192.168.17.2 service 6/22 concurrent-
conns 5
fwaccel dos rate add -i
'<66ad0499,00000000,cd18e2cd,0000677f>' -action notify -log
regular source cidr:10.10.10.10 pkt-rate 20 service any
fwaccel dos rate add -i
'<66ad0470,00000000,cd18e2cd,00006683>' -action notify -log
regular source cidr:1.1.1.10 pkt-rate 20 service any
(3 rules found)
[Expert@MyGW:0]#
```

- Show all DoS / Rate Limiting rules other than ("not") rules with the source value of

"cidr:1.1.1.10":

```
[Expert@MyGW:0]# fwaccel dos rate get -n -k source -v
cidr:1.1.1.10
fwaccel dos rate add -i
'<66b101e7,00000000,cd18e2cd,000019bf>' -action drop -log
regular source cidr:192.168.17.2 service 6/22 concurrent-
conns 5
fwaccel dos rate add -i
'<66ad0499,00000000,cd18e2cd,0000677f>' -action notify -log
regular source cidr:10.10.10.10 pkt-rate 20 service any
(2 rules found)
[Expert@MyGW:0]#
```

- Show all DoS / Rate Limiting rules with the service value of "6/22":

```
[Expert@MyGW:0]# fwaccel dos rate get -k service -v 6/22
fwaccel dos rate add -i
'<66b101e7,00000000,cd18e2cd,000019bf>' -action drop -log
regular source cidr:192.168.17.2 service 6/22 concurrent-
conns 5
(1 rules found)
[Expert@MyGW:0]#
```

## Viewing DoS / Rate Limiting Counters

### Explanation

#### Syntax:

```
{fwaccel | fwaccel6} dos rate
counters --help
counters
counters '<Rule Index>'
counters '<Rule UID>'
```

#### Parameters:

| Parameter | Description                          |
|-----------|--------------------------------------|
| --help}   | Shows the applicable built-in usage. |

| Parameter                                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>counters</code><br><code>'&lt;Rule Index&gt;'</code> | <p>Shows counters for the specified rule.</p> <p>The "&lt;Rule Index&gt;" value is assigned automatically when you add a rule - this is the rule's ordinal number.</p> <p>To see the Index for each rule, run:</p> <pre>{fwaccel   fwaccel6} dos rate get</pre> <p> <b>Notes:</b></p> <ul style="list-style-type: none"> <li>■ The count starts from the top from the number one.</li> <li>■ Use the special Rule Index value "0" to see the global counters.</li> </ul> <p>These counters are used for ratio calculations.</p> <p>For example, when a rule includes a "pkt-rate-ratio" limit.</p> |
| <code>counters</code><br><code>'&lt;Rule UID&gt;'</code>   | <p>Shows counters for the specified rule.</p> <p>The "&lt;Rule Index&gt;" value is assigned automatically when you add a rule.</p> <p>To see the UID for each rule, run:</p> <pre>{fwaccel   fwaccel6} dos rate get</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

**Notes:**

- To reset rule counters, see ["fwaccel dos stats" on page 1550](#).

**Examples:**

- Show the global counters (the Rule Index "0"):

```
[Expert@MyGW:0]# fwaccel dos rate counters 0
(Global Counters)
Concurrent Connections          0
Connection Rate                 0
Packets                         0
Bytes                           0
[Expert@MyGW:0]#
```

- Show counters for the rule with the Rule Index "1":

```

[Expert@MyGW:0]# fwaccel dos rate counters 1

Rule UID
<66b101e7,00000000,cd18e2cd,000019bf>
Policy 1
FW Index 1
SecureXL Index 1
Timeout unlimited
Max Concurrent Connections 5
New Connection Rate unlimited
Packet Rate unlimited
Byte Rate unlimited
Max Concurrent Connections Ratio unlimited
New Connection Rate Ratio unlimited
Packet Rate Ratio unlimited
Byte Rate Ratio unlimited
Action drop
Log Type regular
Concurrent Connections 0
Connection Rate 0
Packets 0
Bytes 0
Packets Dropped 0 (since ratelimiting
policy installed)
Packets Matched 0 (since ratelimiting
policy installed)
Violated Limits (none)
[Expert@MyGW:0]#

```

## fwaccel dos stats

### Description

The "fwaccel dos stats" (for IPv4) and "fwaccel6 dos stats" (for IPv6) commands show and clear the DoS real-time statistics in SecureXL.

#### Important:

- On Scalable Platforms, you must connect to the applicable Security Group. On Scalable Platforms (ElasticXL, Maestro, Scalable Chassis), you must run the required commands only in this way:
  - On the Security Group command line, only on the SMO Security Group Member.
  - In the Global Gaia Clish (`gclish`), must run these commands:
    - `fwaccel dos <Options>`
    - `fwaccel6 dos <Options>`
  - In the Expert mode, must run these commands (start with the "g\_" prefix):
    - `g_fwaccel dos <Options>`
    - `g_fwaccel6 dos <Options>`
- In the VSNext mode / Traditional VSX mode, you must go to the context of an applicable Virtual Gateway / Virtual System.
  - In Gaia Clish, run: `set virtual-system <VSID>`
  - In the Expert mode, run: `vsenv <VSID>`

### Syntax

```
{fwaccel | fwaccel6} dos stats
    {-h | --help}
clear
get
```

## Parameters

| Parameter     | Description                                                                                                                                                                                                                                                                                            |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| No Parameters | Shows the applicable built-in usage.                                                                                                                                                                                                                                                                   |
| -h<br>--help} | Shows the applicable built-in usage.                                                                                                                                                                                                                                                                   |
| clear         | Clears the real-time statistics counters.                                                                                                                                                                                                                                                              |
| get           | <p>Shows the real-time statistics counters.</p> <p> <b>Note</b> - To see the counters for DoS / Rate Limiting rules, run "fwaccel dos rate counters".</p> <p>See <a href="#">"fwaccel dos rate" on page 1528</a>.</p> |

**Example - Get the current DoS statistics**

```
[Expert@MyGW:0]# fwaccel dos stats get

Firewall Instances in Aggregate:

[Expert@MyGW:0]#
```

# fwaccel feature

## Description

The "fwaccel feature" and "fwaccel6 feature" commands enable and disable the specified SecureXL features.

### Important:

- If you disable a SecureXL feature, SecureXL does not accelerate the applicable traffic anymore.
- This change does **not** survive reboot.
- In VSX Gateway, this change is global and applies to all Virtual Systems.
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.

## Syntax for IPv4

```
fwaccel feature <Name of Feature>  
    get  
    off  
    on
```

## Syntax for IPv6

```
fwaccel6 feature <Name of Feature>  
    get  
    off  
    on
```

## Parameters

| Parameter                      | Description                                                                                                                                                                                                                                                  |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| No Parameters                  | Shows the applicable built-in usage.                                                                                                                                                                                                                         |
| <i>&lt;Name of Feature&gt;</i> | Specifies the SecureXL feature.<br>R82.10 SecureXL supports only this feature: <ul style="list-style-type: none"> <li>▪ Name: <code>sctp</code></li> <li>▪ Description: Stream Control Transmission Protocol (SCTP) - see <a href="#">sk35113</a></li> </ul> |
| <code>get</code>               | Shows the current state of the specified SecureXL feature.                                                                                                                                                                                                   |
| <code>off</code>               | Disables the specified SecureXL feature.<br>This means that SecureXL does not accelerate the applicable traffic anymore.                                                                                                                                     |
| <code>on</code>                | Enables the specified SecureXL feature.<br>This means that SecureXL accelerates the applicable traffic again.                                                                                                                                                |

## Disabling the 'sctp' feature permanently

See ["Working with Kernel Parameters" on page 2146](#).

1. Add this line to the `$FWDIR/boot/modules/fwkernel.conf` file:

```
sim_sctp_disable_by_default=1
```

2. Reboot.

## Example 1 - Default output

```
[Expert@MyGW:0]# fwaccel feature
Usage: fwaccel feature <name> {on|off|get}

Available features: sctp
[Expert@MyGW:0]#
```

## Example 2 - Disabling and enabling a feature

```
[Expert@MyGW:0]# fwaccel feature sctp get
sim_sctp_disable_by_default = 0
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel feature sctp off
Set operation succeeded
[Expert@MyGW:0]# fwaccel feature sctp get
sim_sctp_disable_by_default = 1
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel feature sctp on
Set operation succeeded
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel feature sctp get
sim_sctp_disable_by_default = 0
[Expert@MyGW:0]#
```

# fwaccel if

## Description

Shows information about interfaces in SecureXL.

 **Important:**

- On Scalable Platforms, you must connect to the applicable Security Group.
- In the VSNext mode / Traditional VSX mode, you must go to the context of an applicable Virtual Gateway / Virtual System.
  - In Gaia Clish, run: `set virtual-system <VSID>`
  - In the Expert mode, run: `vsenv <VSID>`

## Syntax

|                                                            |
|------------------------------------------------------------|
| <code>fwaccel if -h</code>                                 |
| <code>fwaccel if [<i>&lt;Name of Interface&gt;</i>]</code> |

## Parameters

| Parameter                        | Description                                                                                        |
|----------------------------------|----------------------------------------------------------------------------------------------------|
| <code>-h</code>                  | Shows the applicable built-in usage.                                                               |
| No Parameters                    | Shows the summary table with all interfaces.                                                       |
| <i>&lt;Name of Interface&gt;</i> | Shows the information only for the specified interface.<br>Shows full names of flags and features. |

Examples

Example 1 - Summary table for all interfaces

```
[Expert@MyGW:0]# fwaccel if

=====
SecureXL Device 0

| Device                   | Shows the internal SecureXL Device mask.                                                                                                                                       |

# fwaccel ip\_mr\_cache

## Description

The "fwaccel ip\_mr\_cache" command shows the IPv4 multicast routing cache when SecureXL works in the User Mode (UPPAK) (see [sk153832](#)).

### Important:

- On Scalable Platforms, you must connect to the applicable Security Group.
- In the VSNext mode / Traditional VSX mode, you must go to the context of an applicable Virtual Gateway / Virtual System.
  - In Gaia Clish, run: `set virtual-system <VSID>`
  - In the Expert mode, run: `vsenv <VSID>`

## Syntax for IPv4

```
fwaccel ip_mr_cache
```

## Example

```
[Expert@MyGW:0]# fwaccel ip_mr_cache
Group          Origin      Iif      Wrong      Last Used  Flags      Refcount  Oifs
[Expert@MyGW:0]#
```

# fwaccel nonaccel

## Description

Enables or disables SecureXL acceleration for the specified interfaces.

 **Warning** - If you disable SecureXL acceleration, the performance of the Security Gateway / Cluster Member will decrease. Always consult [Check Point Support](#).

 **Important:**

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.
- In the VSNext mode / Traditional VSX mode, you must go to the context of an applicable Virtual Gateway / Virtual System.
  - In Gaia Clish, run: `set virtual-system <VSID>`
  - In the Expert mode, run: `vsenv <VSID>`

## Syntax

```
fwaccel nonaccel -h
```

```
fwaccel nonaccel {-c | -s} <Name of Interface 1> <Name of  
Interface 2> ... <Name of Interface N>
```

## Parameters

| Parameter           | Description                                                                                                              |
|---------------------|--------------------------------------------------------------------------------------------------------------------------|
| -h                  | Shows the applicable built-in usage.                                                                                     |
| -c                  | Enables SecureXL acceleration for the specified interfaces. This is the default state for all configured interfaces.     |
| -s                  | Disables SecureXL acceleration for the specified interfaces.                                                             |
| <Name of Interface> | Specifies the name of the interface.<br>To see the names of interfaces, run: <a href="#">"fwaccel if" on page 1556</a> . |

## Example

### Example 1 - Disable SecureXL acceleration

```
MyGW> fwaccel nonaccel -s eth1

Interface eth1 set as non-accelerated for SecureXL device 0

Note: changes will not take effect until the interface(s) are restarted.
      (use clish command: set interface <ifname> state [off | on])

MyGW>
MyGW> set interface eth1 state off
MyGW>
MyGW> set interface eth1 state on
MyGW>
MyGW> fwaccel if eth1

=====
SecureXL Device 0
=====
Name:                               eth1

```

# fwaccel off

## Description

The *fwaccel off* and *fwaccel6 off* commands stop the SecureXL on-the-fly.

Starting from R80.20, you can stop the SecureXL only *temporarily*. The SecureXL starts automatically when you start Check Point services (with the ["cpstart" on page 1032](#) command), or reboot the Security Gateway.

### Important:

- Disable the SecureXL only for debug purposes, if Check Point Support explicitly instructs you to do so.
- If you disable the SecureXL, this change does **not** survive reboot. SecureXL remains disabled until you enable it again on-the-fly, or reboot the Security Gateway.
- If you disable the SecureXL, this change applies only to new connections that arrive after you disable the acceleration. SecureXL continues to accelerate the connections that are already accelerated. Other non-connection oriented processing continues to function (for example, virtual defragmentation, VPN decrypt).
- On a VSX Gateway:
  - If you wish to stop the acceleration only for a specific Virtual System, go to the context of that Virtual System.  
In Gaia Clish, run: `set virtual-system <VSID>`  
In Expert mode, run: `vsenv <VSID>`
  - If you wish to stop the acceleration for all Virtual Systems, you must use the "-a" parameter.  
In this case, it does not matter from which Virtual System context you run this command.
- In a Cluster, you must configure all the Cluster Members in the same way.

## Syntax for IPv4

```
fwaccel off [-a] [-q]
```

## Syntax for IPv6

```
fwaccel6 off [-a] [-q]
```

## Parameters

| Parameter | Description                                                  |
|-----------|--------------------------------------------------------------|
| -a        | On a VSX Gateway, stops acceleration on all Virtual Systems. |
| -q        | Suppresses the output (does not show a returned output).     |

## Possible returned output

- SecureXL device disabled
- SecureXL device is not active
- Failed to disable SecureXL device
- fwaccel\_off: failed to set process context <VSID>

## Example 1 - Output from a non-VSX Gateway

```
[Expert@MyGW:0]# fwaccel off
SecureXL device disabled.
[Expert@MyGW:0]#
```

## Example 2 - Output from a VSX Gateway for a specific Virtual System

```
[Expert@MyVSXGW:1]# vsx stat -v

# fwaccel on

## Description

The *fwaccel on* and *fwaccel6 on* commands start the acceleration on-the-fly, if it was previously stopped with the *fwaccel off* or *fwaccel6 off* command (see ["fwaccel off" on page 1564](#)).

### Important:

- On a VSX Gateway:
  - If you wish to start the acceleration only for a specific Virtual System, go to the context of that Virtual System.  
In Gaia Clish, run: `set virtual-system <VSID>`  
In Expert mode, run: `vsenv <VSID>`
  - If you wish to start the acceleration for all Virtual Systems, you must use the "-a" parameter.  
In this case, it does not matter from which Virtual System context you run this command.
- In a Cluster, you must configure all the Cluster Members in the same way.

## Syntax for IPv4

```
fwaccel on [-a] [-q]
```

## Syntax for IPv6

```
fwaccel6 on [-a] [-q]
```

## Parameters

| Parameter | Description                                                       |
|-----------|-------------------------------------------------------------------|
| -a        | On a VSX Gateway, starts the acceleration on all Virtual Systems. |
| -q        | Suppresses the output (does not show a returned output).          |

## Possible returned output

- SecureXL device is enabled.
- Failed to start SecureXL.
- No license for SecureXL.
- SecureXL is disabled by the firewall. Please try again later.

- The installed SecureXL device is not compatible with the installed firewall (version mismatch).
- The SecureXL device is in the process of being stopped. Please try again later.
- SecureXL cannot be started while "flows" are active.
- SecureXL is already started.
- SecureXL will be started after a policy is loaded.
- fwaccel: Failed to check FloodGate-1 status. Acceleration will not be started.
- FW-1: SecureXL acceleration cannot be started while QoS is running in express mode.  
Please disable FloodGate-1 express mode or SecureXL.
- FW-1: SecureXL acceleration cannot be started while QoS is running with citrix printing rule.  
Please remove the citrix printing rule to enable SecureXL.
- FW-1: SecureXL acceleration cannot be started while QoS is running with UAS rule.  
Please remove the UAS rule to enable SecureXL.
- FW-1: SecureXL acceleration cannot be started while QoS is running.  
Please remove the QoS blade to enable SecureXL.
- Failed to enable SecureXL device
- fwaccel\_on: failed to set process context <VSID>

### Example 1 - Output from a non-VSX Gateway

```
[Expert@MyGW:0]# fwaccel on
SecureXL device is enabled.
[Expert@MyGW:0]#
```

# fwaccel ranges

## Description

The *fwaccel ranges* and *fwaccel6 ranges* commands show the SecureXL loaded ranges:

- Ranges of Rule Base source IP addresses
- Ranges of Rule Base destination IP addresses
- Ranges of Rule Base destination ports and protocols

The Security Gateway creates these ranges during the policy installation. The Firewall creates and offloads ranges to SecureXL when any of these feature is enabled:

- Rulebase ranges for Drop Templates
- Anti-Spoofing enforcement ranges on per-interface basis
- NAT64 ranges
- NAT46 ranges

These ranges are related to matching of connections to SecureXL Drop Templates. These ranges represent the **Source**, **Destination** and **Service** columns of the Rule Base.

These ranges are not exactly the same as the Rule Base, because as there are objects that cannot be represented as real (deterministic) IP addresses. For example, Domain objects and Dynamic objects. The Security Gateway converts such non-deterministic objects to "Any" IP address.

In addition, implied rules are represented in these ranges, except for some specific implied rules.

You can use these commands for troubleshooting.

## Syntax for IPv4

```
fwaccel ranges
  -h
  -a
  -l
  -p <Range ID>
  -s <Range ID>
```

## Syntax for IPv6

```
fwaccel6 ranges
    -h
    -a
    -l
    -p <Range ID>
    -s <Range ID>
```

## Parameters

| Parameter                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -h                           | Shows the applicable built-in usage.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| -a<br>or<br>No<br>Parameters | Shows the full information for all loaded ranges.<br><b>Note</b> - In the list of SecureXL Drop Templates (output of the <a href="#">"fwaccel templates" on page 1632</a> command), each Drop Template is assembled from ranges indexes. To see mapping between range index and the range itself, run this command "fwaccel ranges -a". This way you understand better the practical ranges for Drop Templates and when it is appropriate to use them. |
| -l                           | Shows the list of loaded ranges: <ul style="list-style-type: none"> <li>0 - Ranges of Rule Base source IP addresses</li> <li>1 - Ranges of Rule Base destination IP addresses</li> <li>2 - Ranges of Rule Base destination ports and protocols</li> </ul>                                                                                                                                                                                              |
| -p <Range ID>                | Shows the full information for the specified range.                                                                                                                                                                                                                                                                                                                                                                                                    |
| -s <Range ID>                | Shows the summary information for the specified range.                                                                                                                                                                                                                                                                                                                                                                                                 |

## Examples

### Example 1 - Show the list of ranges from a non-VSX Gateway

```
[Expert@MyGW:0]# fwaccel ranges -l
SecureXL device 0:
    0 Rule base source ranges (ip):
    1 Rule base destination ranges (ip):
    2 Rule base dport ranges (port, proto):
[Expert@MyGW:0]#
```

**Example 2 - Show the full information for all loaded ranges from a non-VSX Gateway**

```
[Expert@MyGW:0]# fwaccel ranges
SecureXL device 0:
  Rule base source ranges (ip):
    (0) 0.0.0.0 - 192.168.204.0
    (1) 192.168.204.1 - 192.168.204.1
    (2) 192.168.204.2 - 192.168.204.39
    (3) 192.168.204.40 - 192.168.204.40
    (4) 192.168.204.41 - 192.168.254.39
    (5) 192.168.254.40 - 192.168.254.40
    (6) 192.168.254.41 - 255.255.255.255
  Rule base destination ranges (ip):
    (0) 0.0.0.0 - 192.168.204.0
    (1) 192.168.204.1 - 192.168.204.1
    (2) 192.168.204.2 - 192.168.204.39
    (3) 192.168.204.40 - 192.168.204.40
    (4) 192.168.204.41 - 192.168.254.39
    (5) 192.168.254.40 - 192.168.254.40
    (6) 192.168.254.41 - 255.255.255.255
  Rule base dport ranges (port, proto):
    (0) 0, 0 - 138, 6
    (1) 139, 6 - 139, 6
    (2) 140, 6 - 18189, 6
    (3) 18190, 6 - 18190, 6
    (4) 18191, 6 - 18191, 6
    (5) 18192, 6 - 18192, 6
    (6) 18193, 6 - 19008, 6
    (7) 19009, 6 - 19009, 6
    (8) 19010, 6 - 136, 17
    (9) 137, 17 - 138, 17
    (10) 139, 17 - 65535, 65535
[Expert@MyGW:0]#
```

**Example 3 - Show the full information for the specified range from a non-VSX Gateway**

```
[Expert@MyGW:0]# fwaccel ranges -p 0
SecureXL device 0:
  Rule base source ranges (ip):
    (0) 0.0.0.0 - 192.168.204.0
    (1) 192.168.204.1 - 192.168.204.1
    (2) 192.168.204.2 - 192.168.204.39
    (3) 192.168.204.40 - 192.168.204.40
    (4) 192.168.204.41 - 192.168.254.39
    (5) 192.168.254.40 - 192.168.254.40
    (6) 192.168.254.41 - 255.255.255.255
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel ranges -p 1
SecureXL device 0:

# fwaccel stat

## Description

The *fwaccel stat* and *fwaccel6 stat* commands show this information on the Security Gateway, or Cluster Member:

Shows this information:

| Column     | Information                      |
|------------|----------------------------------|
| Id         | Always 0.                        |
| Name       | SecureXL mode.                   |
| Status     | Enabled or Disabled.             |
| Interfaces | Names of accelerated interfaces. |
| Features   | Names of accelerated features.   |

In addition, these command show the status of these features (enabled or disabled):

- SecureXL Accept Templates.
- SecureXL Drop Templates.
- SecureXL NAT Templates.
- SecureXL status of LightSpeed Acceleration.

## Syntax for IPv4

```
fwaccel stat
```

## Syntax for IPv6

```
fwaccel6 stat
```

## Example

- This output is from a Security Gateway (non-VSX).
- SecureXL works in the User Space (UPPAK) mode.
- SecureXL is enabled.
- SecureXL accelerates the interfaces eth0 and eth1.

```
[Expert@MyGW:0]# fwaccel stat
+-----+
|Id|Name      |Status    |Interfaces      |Features          |
+-----+
|0 |UPPAK     |enabled   |eth0,eth1       |Acceleration,Cryptography |
| |          |          |                |Crypto: Tunnel,UDPEncap,MD5, |
| |          |          |                |SHA1,3DES,DES,AES-128,AES-256, |
| |          |          |                |ESP,LinkSelection,DynamicVPN, |
| |          |          |                |NatTraversal,AES-XCBC,SHA256, |
| |          |          |                |SHA384,SHA512          |
+-----+

Accept Templates : enabled
Drop Templates   : disabled
NAT Templates    : enabled
LightSpeed Accel : disabled
[Expert@MyGW:0]#
```

# fwaccel stats

## Description

The *fwaccel stats* and *fwaccel6 stats* commands show acceleration statistics for IPv4 on the local Security Gateway, or Cluster Member.

## Syntax for IPv4

```
fwaccel stats
    [-c]
    [-d]
    [-l]
    [-m]
    [-n]
    [-o]
    [-p]
    [-q]
    [-r]
    [-s]
    [-x]
```

## Syntax for IPv6

```
fwaccel6 stats
    [-c]
    [-d]
    [-l]
    [-m]
    [-n]
    [-o]
    [-p]
    [-q]
    [-r]
    [-s]
    [-x]
```

## Parameters

| Parameter | Description                                                                                                                                                                                           |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -c        | Shows the statistics for Cluster Correction.                                                                                                                                                          |
| -d        | Shows the statistics for drops from device.                                                                                                                                                           |
| -l        | Shows the statistics in legacy mode - as one table.                                                                                                                                                   |
| -m        | Shows the statistics for multicast traffic.                                                                                                                                                           |
| -n        | Shows the statistics for Identity Awareness (NAC).                                                                                                                                                    |
| -o        | Shows the statistics for Reorder Infrastructure.<br> <b>Note</b> - Scalable Platforms do not support this parameter. |
| -p        | Shows the statistics for SecureXL violations (F2F packets).                                                                                                                                           |
| -q        | Shows the statistics notifications the SecureXL sent to the Firewall.                                                                                                                                 |
| -r        | Resets all the counters.                                                                                                                                                                              |
| -s        | Shows the statistics summary only.                                                                                                                                                                    |
| -x        | Shows the statistics for PXL.<br><b>Note</b> - PXL is the technology name for combination of SecureXL and PSL (Passive Streaming Library).                                                            |

## Description of the Statistics Counters in the "fwaccel stats" Output

### The "Accelerated Path" section

| Counter              | Description                                                                              |
|----------------------|------------------------------------------------------------------------------------------|
| accel packets        | Number of accelerated packets.                                                           |
| accel bytes          | Number of accelerated bytes.                                                             |
| outbound packets     | Number of outbound packets.                                                              |
| outbound bytes       | Number of outbound bytes.                                                                |
| conns created        | Number of connections the SecureXL created.                                              |
| conns deleted        | Number of connections the SecureXL deleted.                                              |
| C total conns        | Total number of connections the SecureXL currently handles.                              |
| C templates          | <i>Not in use</i><br>Total number of SecureXL templates the SecureXL currently handles.  |
| C TCP conns          | Number of TCP connections the SecureXL currently handles.                                |
| C non TCP conns      | Number of non-TCP connections the SecureXL currently handles.                            |
| conns from templates | <i>Not in use</i><br>Number of connections the SecureXL created from SecureXL templates. |
| nat conns            | Number of NAT connections.                                                               |
| dropped packets      | Number of packets the SecureXL dropped.                                                  |
| dropped bytes        | Number of bytes the SecureXL dropped.                                                    |
| nat templates        | <i>Not in use</i>                                                                        |
| port alloc templates | <i>Not in use</i>                                                                        |
| conns from nat tmpl  | <i>Not in use</i>                                                                        |
| port alloc conns     | <i>Not in use</i>                                                                        |

| Counter             | Description                                               |
|---------------------|-----------------------------------------------------------|
| fragments received  | Number of received fragments.                             |
| fragments transmit  | Number of transmitted fragments.                          |
| fragments dropped   | Number of dropped fragments.                              |
| fragments expired   | Number of expired fragments.                              |
| IP options stripped | Number of packets, from SecureXL stripped IP options.     |
| IP options restored | Number of packets, in which SecureXL restored IP options. |
| IP options dropped  | Number of packets with IP options that SecureXL dropped.  |
| corrs created       | Number of corrections the SecureXL made.                  |
| corrs deleted       | Number of corrections the SecureXL deleted.               |
| C corrections       | Number of corrections the SecureXL currently handles.     |
| corrected packets   | Number of corrected packets.                              |
| corrected bytes     | Number of corrected bytes.                                |

## The "Accelerated VPN Path" section

| Counter          | Description                                                     |
|------------------|-----------------------------------------------------------------|
| C crypt conns    | Number of encrypted connections the SecureXL currently handles. |
| enc bytes        | Number of encrypted traffic bytes.                              |
| dec bytes        | Number of decrypted traffic bytes.                              |
| ESP enc pkts     | Number of ESP encrypted packets.                                |
| ESP enc err      | Number of ESP encryption errors.                                |
| ESP dec pkts     | Number of ESP decrypted packets.                                |
| ESP dec err      | Number of ESP decryption errors.                                |
| ESP other err    | Number of ESP general errors.                                   |
| espudp enc pkts  | <i>Not in use</i>                                               |
| espudp enc err   | <i>Not in use</i>                                               |
| espudp dec pkts  | <i>Not in use</i>                                               |
| espudp dec err   | <i>Not in use</i>                                               |
| espudp other err | <i>Not in use</i>                                               |

## The "Medium Streaming Path" section

| Counter           | Description                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PXL packets       | Number of PXL packets.<br>PXL is combination of SecureXL and Passive Streaming Library (PSL), which is an IPS infrastructure that transparently listens to TCP traffic as network packets, and rebuilds the TCP stream out of these packets. Passive Streaming can listen to all TCP traffic, but process only the data packets, which belong to a previously registered connection. |
| PXL async packets | Number of PXL packets the SecureXL handled asynchronously.                                                                                                                                                                                                                                                                                                                           |
| PXL bytes         | Number of PXL bytes.                                                                                                                                                                                                                                                                                                                                                                 |
| C PXL conns       | Number of PXL connections the SecureXL currently handles.                                                                                                                                                                                                                                                                                                                            |
| C PXL templates   | <i>Not in use</i><br>Number of PXL templates.                                                                                                                                                                                                                                                                                                                                        |
| PXL FF conns      | Number of PXL Fast Forward connections.                                                                                                                                                                                                                                                                                                                                              |
| PXL FF packets    | Number of PXL Fast Forward packets.                                                                                                                                                                                                                                                                                                                                                  |
| PXL FF bytes      | Number of PXL Fast Forward bytes.                                                                                                                                                                                                                                                                                                                                                    |
| PXL FF acks       | Number of PXL Fast Forward acknowledgments.                                                                                                                                                                                                                                                                                                                                          |

## The "Inline Streaming Path" section

| Counter             | Description                         |
|---------------------|-------------------------------------|
| PSL Inline packets  | Number of accelerated PSL packets.  |
| PSL Inline bytes    | Number of accelerated PSL bytes.    |
| CPAS Inline packets | Number of accelerated CPAS packets. |
| CPAS Inline bytes   | Number of accelerated CPAS bytes.   |

## The "QoS General Information" section

| Counter              | Description                           |
|----------------------|---------------------------------------|
| Total QoS Conns      | Total number of QoS connections.      |
| QoS Classify Conns   | Number of classified QoS connections. |
| QoS Classify flow    | Number of classified QoS flows.       |
| Reclassify QoS polic | Number of reclassify QoS requests.    |

## The "Firewall QoS Path" section

| Counter              | Description                                                 |
|----------------------|-------------------------------------------------------------|
| Enqueued IN packets  | Number of waiting packets in Firewall QoS inbound queue.    |
| Enqueued OUT packets | Number of waiting packets in Firewall QoS outbound queue.   |
| Dequeued IN packets  | Number of processed packets in Firewall QoS inbound queue.  |
| Dequeued OUT packets | Number of processed packets in Firewall QoS outbound queue. |
| Enqueued IN bytes    | Number of waiting bytes in Firewall QoS inbound queue.      |
| Enqueued OUT bytes   | Number of waiting bytes in Firewall QoS outbound queue.     |
| Dequeued IN bytes    | Number of processed bytes in Firewall QoS inbound queue.    |
| Dequeued OUT bytes   | Number of processed bytes in Firewall QoS outbound queue.   |

## The "Accelerated QoS Path" section

| Counter              | Description                                                 |
|----------------------|-------------------------------------------------------------|
| Enqueued IN packets  | Number of waiting packets in SecureXL QoS inbound queue.    |
| Enqueued OUT packets | Number of waiting packets in SecureXL QoS outbound queue.   |
| Dequeued IN packets  | Number of processed packets in SecureXL QoS inbound queue.  |
| Dequeued OUT packets | Number of processed packets in SecureXL QoS outbound queue. |
| Enqueued IN bytes    | Number of waiting bytes in SecureXL QoS inbound queue.      |
| Enqueued OUT bytes   | Number of waiting bytes in SecureXL QoS outbound queue.     |
| Dequeued IN bytes    | Number of processed bytes in SecureXL QoS inbound queue.    |
| Dequeued OUT bytes   | Number of processed bytes in SecureXL QoS outbound queue.   |

## The "Firewall Path" section

| Counter             | Description                                                                                                       |
|---------------------|-------------------------------------------------------------------------------------------------------------------|
| F2F packets         | Number of packets that SecureXL forwarded to the Firewall kernel in Slow Path.                                    |
| F2F bytes           | Number of bytes that SecureXL forwarded to the Firewall kernel in Slow Path.                                      |
| TCP violations      | Number of packets, which are in violation of the TCP state.                                                       |
| C anticipated conns | Number of anticipated connections SecureXL currently handles.                                                     |
| port alloc f2f      | <i>Not in use</i>                                                                                                 |
| F2V conn match pkts | Number of packets that matched a SecureXL connection and SecureXL forwarded to the Firewall kernel.               |
| F2V packets         | Number of packets that SecureXL forwarded to the Firewall kernel and the Firewall re-injected back to SecureXL.   |
| F2V bytes           | Number of bytes that SecureXL forwarded to the Firewall kernel and the Firewall re-injected back to the SecureXL. |

**The "GTP" section**

| Counter             | Description                                                          |
|---------------------|----------------------------------------------------------------------|
| gtp tunnels created | Number of created GTP tunnels.                                       |
| gtp tunnels         | Number of GTP tunnels the SecureXL currently handles.                |
| gtp accel pkts      | Number of accelerated GTP packets.                                   |
| gtp f2f pkts        | Number of GTP packets the SecureXL forwarded to the Firewall kernel. |
| gtp spoofed pkts    | Number of spoofed GTP packets.                                       |
| gtp in gtp pkts     | Number of GTP-in-GTP packets.                                        |
| gtp signaling pkts  | Number of signaling GTP packets.                                     |
| gtp tcptopt pkts    | Number of GTP packets with TCP Options.                              |
| gtp apn err pkts    | Number of GTP packets with APN errors.                               |

**The "GRE" section**

| Counter                  | Description                                                          |
|--------------------------|----------------------------------------------------------------------|
| gre accel inbound pkts   | Number of inbound accelerated GRE packets.                           |
| gre accel outbound pkts  | Number of outbound accelerated GRE packets.                          |
| gre accel inbound bytes  | Number of inbound accelerated GRE bytes.                             |
| gre accel outbound bytes | Number of outbound accelerated GRE bytes.                            |
| gre accel f2f pkts       | Number of GRE packets the SecureXL forwarded to the Firewall kernel. |
| gre accel total conns    | Total number of GRE connections.                                     |

## The "VXLAN" section

| Counter                                 | Description                                                            |
|-----------------------------------------|------------------------------------------------------------------------|
| <code>vxlan accel inbound pkts</code>   | Number of inbound accelerated VXLAN packets.                           |
| <code>vxlan accel outbound pkts</code>  | Number of outbound accelerated VXLAN packets.                          |
| <code>vxlan accel inbound bytes</code>  | Number of inbound accelerated VXLAN bytes.                             |
| <code>vxlan accel outbound bytes</code> | Number of outbound accelerated VXLAN bytes.                            |
| <code>vxlan accel f2f pkts</code>       | Number of VXLAN packets the SecureXL forwarded to the Firewall kernel. |
| <code>vxlan accel total conns</code>    | Total number of VXLAN connections.                                     |

## The "General" section

| Counter              | Description                                                                                       |
|----------------------|---------------------------------------------------------------------------------------------------|
| memory used          | <i>Not in use</i>                                                                                 |
| free memory          | <i>Not in use</i>                                                                                 |
| C used templates     | <i>Not in use</i>                                                                                 |
| pxl tmpl conns       | <i>Not in use</i>                                                                                 |
| C conns from tmpl    | <i>Not in use</i><br>Number of current connections that SecureXL created from SecureXL Templates. |
| C tcp handshake conn | Number of current TCP connections that are not yet established.                                   |
| C tcp established co | Number of established TCP connections the SecureXL currently handles.                             |
| C tcp closed conns   | Number of closed TCP connections the SecureXL currently handles.                                  |
| C tcp pxl handshake  | Number of not yet established PXL TCP connections the SecureXL currently handles.                 |
| C tcp pxl establishe | Number of established PXL TCP connections the SecureXL currently handles.                         |
| C tcp pxl closed con | Number of closed PXL TCP connections the SecureXL currently handles.                              |
| outbound pxl packets | <i>Not in use</i>                                                                                 |

## Example Outputs on the "fwaccel stats" Commands

### Example: fwaccel stats -s

Example of statistics summary:

```
Accelerated conns/Total conns : 0/0 (0%)  
Accelerated pkts/Total pkts   : 0/8 (0%)  
F2Fed pkts/Total pkts        : 8/8 (100%)  
F2V pkts/Total pkts          : 0/8 (0%)  
CPASXL pkts/Total pkts       : 0/8 (0%)  
PSLXL pkts/Total pkts        : 0/8 (0%)  
QOS inbound pkts/Total pkts  : 0/8 (0%)  
QOS outbound pkts/Total pkts : 0/8 (0%)  
Corrected pkts/Total pkts     : 0/8 (0%)
```

### Example: fwaccel stats

Example of the default output:

## Example Outputs on the "fwaccel stats" Commands

| Name                     | Value | Name                  | Value   |
|--------------------------|-------|-----------------------|---------|

| No resources                    | 0     | Hold timeout           | 0     |

# fwaccel synatk

## Description

The *fwaccel synatk* and *fwaccel6 synatk* commands control the Accelerated SYN Defender on the local Security Gateway, or Cluster Member.

### Important:

- See [sk120476](#) for information about the 'SYN Attack' protection in SmartConsole.
- In a Scalable Platform, the same SecureXL command must run on all Security Group Members.  
Therefore, you must run the SecureXL commands in either Gaia gClish, or Expert mode.
  - In Gaia gClish, run the "fwaccel ..." and "fwaccel6 ..." commands.
  - In the Expert mode, run the "g\_fwaccel ..." and "g\_fwaccel6 ..." commands.
- In a Scalable Platform, when you add a new Security Group Member to a Security Group, the new Security Group Member pulls the "fwaccel synatk" configuration that you saved it in a configuration file - in the default file `$FWDIR/conf/synatk.conf`, or in the file specified with the "fwaccel synatk -c" command.

## Syntax for IPv4

```
fwaccel synatk
  -a
  -c <options>
  -d
  -e
  -g
  -m
  -t <options>
  config
  monitor <options>
  state <options>
  whitelist <options>
```

## Syntax for IPv6

```
fwaccel6 synatk
  -a
  -c <options>
  -d
  -e
  -g
  -m
  -t <options>
  config
  monitor <options>
  state <options>
  whitelist <options>
```

## Parameters

| Parameter       | Description                                                                                                                                                                                                                                                |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| No Parameters   | Shows the applicable built-in usage.                                                                                                                                                                                                                       |
| -a              | Applies the configuration from the default file.<br>See <a href="#">"fwaccel synatk -a" on page 1606</a> .                                                                                                                                                 |
| -c<br><options> | Applies the configuration from the specified file.<br>See <a href="#">"fwaccel synatk -c &lt;Configuration File&gt;" on page 1607</a> .                                                                                                                    |
| -d              | Disables the Accelerated SYN Defender on all interfaces.<br>See <a href="#">"fwaccel synatk -d" on page 1608</a> .                                                                                                                                         |
| -e              | Enables the Accelerated SYN Defender on interfaces with topology "External".<br>Enables the Accelerated SYN Defender in Monitor (Detect only) mode on interfaces with topology "Internal".<br>See <a href="#">"fwaccel synatk -e" on page 1609</a> .       |
| -g              | Enables the Accelerated SYN Defender on all interfaces.<br>See <a href="#">"fwaccel synatk -g" on page 1610</a> .                                                                                                                                          |
| -m              | Enables the Accelerated SYN Defender in Monitor (Detect only) mode on all interfaces.<br>In this state, the Accelerated SYN Defender only sends a log when it recognizes a TCP SYN Flood attack.<br>See <a href="#">"fwaccel synatk -m" on page 1611</a> . |

| Parameter                                            | Description                                                                                                                                                                            |
|------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-t</code><br><code>&lt;options&gt;</code>      | Configures the threshold numbers of half-opened TCP connections that trigger the Accelerated SYN Defender.<br>See <a href="#">"fwaccel synatk -t &lt;Threshold&gt;" on page 1612</a> . |
| <code>config</code>                                  | Shows the current Accelerated SYN Defender configuration.<br>See <a href="#">"fwaccel synatk config" on page 1619</a> .                                                                |

## fwaccel synatk -a

### Description

The "*fwaccel synatk -a*" and "*fwaccel6 synatk -a*" commands apply the Accelerated SYN Defender configuration from the default `$FWDIR/conf/synatk.conf` file.

#### Notes:

- Both IPv4 and IPv6 use the same configuration file.
- Interface specific state settings that you define in the configuration file, override the settings that you define with these commands:
  - "*fwaccel synatk -d*" on page 1608
  - "*fwaccel synatk -e*" on page 1609
  - "*fwaccel synatk -g*" on page 1610
  - "*fwaccel synatk -m*" on page 1611

### Syntax for IPv4

```
fwaccel synatk -a
```

### Syntax for IPv6

```
fwaccel6 synatk -a
```

## fwaccel synatk -c <Configuration File>

### Description

The "*fwaccel synatk -c <Configuration File>*" and "*fwaccel6 synatk -c <Configuration File>*" commands apply the Accelerated SYN Defender configuration from the specified file.

**Important** - If you use this parameter, then it must be the first parameter in the syntax.

#### Notes:

- Both IPv4 and IPv6 use the same configuration file.
- The state settings of a specific interface that you define in the configuration file, override the settings that you define with these commands:
  - "*fwaccel synatk -d*" [on page 1608](#)
  - "*fwaccel synatk -e*" [on page 1609](#)
  - "*fwaccel synatk -g*" [on page 1610](#)
  - "*fwaccel synatk -m*" [on page 1611](#)

### Syntax for IPv4

```
fwaccel synatk -c <Configuration File>
```

### Syntax for IPv6

```
fwaccel6 synatk -c <Configuration File>
```

### Parameters

| Parameter                         | Description                                                                                                           |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| <i>&lt;Configuration File&gt;</i> | Specifies the full path and the name of the file.<br>For reference, see the default file:<br>\$FWDIR/conf/synatk.conf |

## fwaccel synatk -d

### Description

The "*fwaccel synatk -d*" and "*fwaccel6 synatk -d*" commands disable the Accelerated SYN Defender on all interfaces.

#### Notes:

- This command:
  1. Modifies the default configuration file `$FWDIR/conf/synatk.conf`, or the configuration file specified with the "`-c`" parameter.
  2. Loads the modified file.
  3. Does not show any output.
- Output of the "*fwaccel synatk monitor*" on page 1622 command shows:
  - In the row "Configuration": Disabled
  - In the column "Enforce": Disable
  - In the column "State (sec)": Disable
- Output of the "*fwaccel synatk config*" on page 1619 command shows:
  - In the row "enabled": 0
  - In the row "enforce": 0

### Syntax for IPv4

```
fwaccel synatk -d
```

### Syntax for IPv6

```
fwaccel6 synatk -d
```

## fwaccel synatk -e

### Description

The "*fwaccel synatk -e*" and "*fwaccel6 synatk -e*" commands:

- Enable the Accelerated SYN Defender on interfaces with topology "External".
- Enable the Accelerated SYN Defender in Monitor (Detect only) mode on interfaces with topology "Internal".

### Notes:

- This command:
  1. Modifies the default configuration file `$FWDIR/conf/synatk.conf`, or the configuration file specified with the "`-c`" parameter.
  2. Loads the modified file.
- Output of the "*fwaccel synatk monitor*" on page 1622 command shows for "External" interfaces:
  - Configuration: Enforcing
  - Enforce: Prevent
  - State: Ready (may change later depending on what the SYN Defender detects)
- Output of the "*fwaccel synatk monitor*" on page 1622 command shows for "Internal" interfaces:
  - Configuration: Enforcing
  - Enforce: Detect
  - State: Monitor
- Output of the "*fwaccel synatk config*" on page 1619 command shows:
  - enabled 1
  - enforce 1

### Syntax for IPv4

```
fwaccel synatk -e
```

### Syntax for IPv6

```
fwaccel6 synatk -e
```

## fwaccel synatk -g

### Description

The "*fwaccel synatk -g*" and "*fwaccel6 synatk -g*" commands enable the Accelerated SYN Defender on all interfaces.

#### Notes:

- This command:
  1. Modifies the default configuration file `$FWDIR/conf/synatk.conf`, or the configuration file specified with the "`-c`" parameter.
  2. Loads the modified file.
- Output of the "*fwaccel synatk monitor*" on page 1622 command shows for "External" interfaces:
  - Configuration: Enforcing
  - Enforce: Prevent
  - State: Ready (may change later depending on what the SYN Defender detects)
- Output of the "*fwaccel synatk monitor*" on page 1622 command shows for "Internal" interfaces:
  - Configuration: Enforcing
  - Enforce: Detect
  - State: Monitor
- Output of the "*fwaccel synatk config*" on page 1619 command shows:
  - enabled 1
  - enforce 2

### Syntax for IPv4

```
fwaccel synatk -g
```

### Syntax for IPv6

```
fwaccel6 synatk -g
```

## fwaccel synatk -m

### Description

The "*fwaccel synatk -m*" and "*fwaccel6 synatk -m*" commands enable the Accelerated SYN Defender in Monitor (Detect only) mode on all interfaces.

In this state, the Accelerated SYN Defender only sends a log when it recognizes a TCP SYN Flood attack.

#### Notes:

- This command:
  1. Modifies the default configuration file `$FWDIR/conf/synatk.conf`, or the configuration file specified with the "`-c`" parameter.
  2. Loads the modified file.
- Output of the "*fwaccel synatk monitor*" on page 1622 command shows:
  - Configuration: Monitoring
  - Enforce: Detect
  - State: Monitor
- Output of the "*fwaccel synatk config*" on page 1619 command shows:
  - enabled 1
  - enforce 0

### Syntax for IPv4

```
fwaccel synatk -m
```

### Syntax for IPv6

```
fwaccel6 synatk -m
```

## fwaccel synatk -t <Threshold>

### Description

The "*fwaccel synatk -t <Threshold>*" and "*fwaccel6 synatk -t <Threshold>*" commands configure the threshold numbers of half-opened TCP connections that trigger the Accelerated SYN Defender.

#### Notes:

- This command:
  1. Modifies the default configuration file `$FWDIR/conf/synatk.conf`, or the configuration file specified with the "-c" parameter.
  2. Loads the modified file.
- Threshold values are independent for IPv4 and IPv6.

### Syntax for IPv4

```
fwaccel synatk -t <Threshold>
```

### Syntax for IPv6

```
fwaccel6 synatk -t <Threshold>
```

## Thresholds

- The **Global high attack threshold** number is configured to the specified value *<Threshold>*.

This is the number of half-open TCP connections on all interfaces required for the Accelerated SYN Defender to engage.

- Valid values: 100 and greater
- Default: 10000

- The **High attack threshold** number is configured to 1/2 of the specified value *<Threshold>*.

This is the high number of half-open TCP connections on an interface required for the Accelerated SYN Defender to engage.

- Valid values: (Low attack threshold) < (High attack threshold) <= (Global high attack threshold)
- Default: 5000

- The **Low attack threshold** number is configured to 1/10 of the specified value *<Threshold>*.

This is the low number of half-open TCP connections on an interface required for the Accelerated SYN Defender to engage.

- Valid values: 10 and greater
- Default: 1000

# fwaccel synatk allow

## Description

The "*fwaccel synatk allow*" and "*fwaccel6 synatk allow*" commands control the Accelerated SYN Defender allow-list.

### Notes:

- This allow-list overrides which packet the Accelerated SYN Defender drops. Before you use a 3rd-party or automatic blacklists, add trusted networks and hosts to the allow-list to avoid outages.
- Also, see the "*fwaccel dos allow*" on page 1487 command.

 **Important** - In Cluster, you must configure the Rate Limiting in the same way on all the Cluster Members.

## Syntax for IPv4

```
fwaccel synatk allow
  -a <IPv4 Address>[/<Subnet Prefix>]
  -d <IPv4 Address>[/<Subnet Prefix>]
  -F
  -l /<Path>/<Name of File>
  -L
  -s
```

## Syntax for IPv6

```
fwaccel6 synatk allow
  -a <IPv6 Address>[/<Subnet Prefix>]
  -d <IPv6 Address>[/<Subnet Prefix>]
  -F
  -l /<Path>/<Name of File>
  -L
  -s
```

## Parameters

| Parameter     | Description                          |
|---------------|--------------------------------------|
| No Parameters | Shows the applicable built-in usage. |

| Parameter                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Example

```
[Expert@MyGW:0]# fwaccel synatk allow -a 192.168.20.0/24
[Expert@MyGW:0]# fwaccel synatk allow -s
192.168.20.0/24
[Expert@MyGW:0]# fwaccel synatk allow -d 192.168.20.0/24
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel synatk allow -a 192.168.40.55
[Expert@MyGW:0]# fwaccel synatk allow -s
192.168.40.55/32
[Expert@MyGW:0]# fwaccel synatk allow -d 192.168.40.55
```

## fwaccel synatk config

### Description

The "*fwaccel synatk config*" and "*fwaccel6 synatk config*" commands show the current Accelerated SYN Defender configuration.

### Syntax for IPv4

```
fwaccel synatk config
```

### Syntax for IPv6

```
fwaccel6 synatk config
```

### Example

```
[Expert@MyGW:0]# fwaccel synatk config
enabled 0
enforce 1
global_high_threshold 10000
periodic_updates 1
cookie_resolution_shift 6
min_frag_sz 80
high_threshold 5000
low_threshold 1000
score_alpha 100
monitor_log_interval (msec) 60000
grace_timeout (msec) 30000
min_time_in_active (msec) 60000
[Expert@MyGW:0]#
```

## Description of Configuration Parameters

| Parameter               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

# fwaccel synatk monitor

## Description

The "*fwaccel synatk monitor*" and "*fwaccel6 synatk monitor*" commands show the Accelerated SYN Defender status.

 **Important** - To enable the Accelerated SYN Defender in Monitor (Detect only) mode on all interfaces, you must run the "*fwaccel synatk -m on page 1611*" command.

## Syntax for IPv4

```
fwaccel synatk monitor
  [-p]
  [-p] -a
  [-p] -s
  [-p] -v
```

## Syntax for IPv6

```
fwaccel6 synatk monitor
  [-p]
  [-p] -a
  [-p] -s
  [-p] -v
```

## Parameters

 **Important** - You can specify only one of these parameters: -a, -s, or -v.

| Parameter | Description                                                                                                         |
|-----------|---------------------------------------------------------------------------------------------------------------------|
| -p        | Shows the Accelerated SYN Defender status for each SecureXL instance ("PPAK ID: 0" is the Host Security Appliance). |
| [-p] -a   | Shows the Accelerated SYN Defender statistics for all interfaces (for each SecureXL instance).                      |
| [-p] -s   | Shows the attack state in short form (for each SecureXL instance).                                                  |
| [-p] -v   | Shows the attack state in verbose form (for each SecureXL instance).                                                |

## Examples

### Example 1 - Default output before and after enabling the Accelerated SYN Defender

```
[Expert@MyGW:0]# fwaccel synatk monitor
+-----+
| SYN Defender status                                     |
+-----+
| Configuration                                           Disabled |
| Status                                                  Normal |
| Non established connections                             0      |
| Global Threshold                                       10000 |
| Interface Threshold                                    5000  |
+-----+
| IF              | Topology | Enforce | State (sec) | Non-established conns |
|                 |          |         |             | Peak                 |
|                 |          |         |             | Current              |
+-----+
| eth0            | External | Disable | Disable     | N/A                  |
| eth1            | Internal | Disable | Disable     | N/A                  |
+-----+

[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel synatk -m
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel synatk monitor
+-----+
| SYN Defender status                                     |
+-----+
| Configuration                                           Monitoring |
| Status                                                  Normal |
| Non established connections                             0      |
| Global Threshold                                       10000 |
| Interface Threshold                                    5000  |
+-----+
| IF              | Topology | Enforce | State (sec) | Non-established conns |
|                 |          |         |             | Peak                 |
|                 |          |         |             | Current              |
+-----+
| eth0            | External | Detect  | Monitor     | 0                    |
| eth1            | Internal | Detect  | Monitor     | 0                    |
+-----+

[Expert@MyGW:0]#
```

**Example 2 - Showing the Accelerated SYN Defender status for each SecureXL instance**

```
[Expert@MyGW:0]# fwaccel synatk monitor -p
```

## fwaccel synatk state

### Description

The "*fwaccel synatk state*" and "*fwaccel6 synatk state*" commands control the Accelerated SYN Defender states.

The states are independent for IPv4 and IPv6.

 **Important** - This command is **not** intended for end-user usage. Transitions between states (Ready, Grace, and Active) occur automatically. This command provides a way to force temporarily a state transition on an interface or group of interfaces.

### Syntax for IPv4

```
fwaccel synatk state
  -h
  -a
  -d
  -g
  -i {all | external | internal | <Name of Interface>}
  -m
  -r
```

### Syntax for IPv6

```
fwaccel6 synatk state
  -h
  -a
  -d
  -g
  -i {all | external | internal | <Name of Interface>}
  -m
  -r
```

## Parameters

**Important** - You can specify only one of these parameters: `-a`, `-d`, `-g`, `-m`, or `-r`.

| Parameter                                 | Description                                                 |
|-------------------------------------------|-------------------------------------------------------------|
| <code>-h</code>                           | Shows the applicable built-in usage.                        |
| <code>-a</code>                           | Sets the state to Active.                                   |
| <code>-d</code>                           | Sets the state to Disabled.                                 |
| <code>-g</code>                           | Sets the state to Grace.                                    |
| <code>-i all</code>                       | Applies the change to all interfaces (this is the default). |
| <code>-i external</code>                  | Applies the change only to external interfaces.             |
| <code>-i internal</code>                  | Applies the change only to internal interfaces.             |
| <code>-i &lt;Name of Interface&gt;</code> | Applies the change to the specified interface.              |
| <code>-m</code>                           | Sets the state to Monitor (Detect only) mode.               |
| <code>-r</code>                           | Sets the state to Ready.                                    |

# fwaccel tab

## Description

The *fwaccel tab* and *fwaccel6 tab* commands show the contents of the specified SecureXL kernel table.

### Notes:

- Dynamic tables, such as the `connections` table can change while this command prints their contents.  
This may cause some values to be missed or reported twice.
- For some tables, the command prints their contents on the screen.
- For some tables, the command prints their contents to the `/var/log/messages` file.
- Also, see the ["fw tab" on page 1264](#) command.

## Syntax for IPv4

```
fwaccel tab [-f] [-m <Number of Rows>] -t <Name of Kernel Table>
fwaccel tab -s -t <Name of Kernel Table>
```

## Syntax for IPv6

```
fwaccel6 tab [-f] [-m <Number of Rows>] -t <Name of Kernel Table>
fwaccel6 tab -s -t <Name of Kernel Table>
```

## Parameters

| Parameter           | Description                                                                                                                      |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------|
| No Parameters       | Shows the applicable built-in usage.                                                                                             |
| -f                  | Formats the output.<br>We recommend to always use this parameter.                                                                |
| -m <Number of Rows> | Specifies how many rows to show from the kernel table.<br>Note - The command counts from the top of the table.<br>Default : 1000 |
| -s                  | Shows summary information only.                                                                                                  |

| Parameter                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-t &lt;Name of Kernel Table&gt;</code> | <p>Specifies the kernel table.</p> <p>This command supports only these kernel tables:</p> <ul style="list-style-type: none"> <li>■ connections</li> <li>■ dos_ip_blacklists</li> <li>■ dos_pbox</li> <li>■ dos_pbox_violating_ips</li> <li>■ dos_rate_matches</li> <li>■ dos_rate_track_src</li> <li>■ dos_rate_track_src_svc</li> <li>■ drop_templates</li> <li>■ frag_table</li> <li>■ gtp_apns</li> <li>■ gtp_tunnels</li> <li>■ if_by_name</li> <li>■ inbound_SAs</li> <li>■ invalid_replay_counter</li> <li>■ ipsec_mtu_icmp</li> <li>■ mcast_drop_conns</li> <li>■ outbound_SAs</li> <li>■ PMTU_table</li> <li>■ &lt;Profile&gt;</li> <li>■ reset_table</li> <li>■ vpn_link_selection</li> <li>■ vpn_trusted_ifs</li> </ul> |

## Examples

```
[Expert@MyGW:0]# fwaccel tab -f -m 200 -t connections
Table connections is empty
[Expert@MyGW:0]#
```

```
[Expert@MyGW:0]# fwaccel tab -t inbound_SAs
Table contents written to /var/log/messages.
[Expert@MyGW:0]#
```

```
[Expert@MyGW:0]# fwaccel tab -t outbound_SAs
Table contents written to /var/log/messages.
[Expert@MyGW:0]#
```

```
[Expert@MyGW:0]# fwaccel tab -t vpn_link_selection
Table contents written to /var/log/messages.
[Expert@MyGW:0]#
```

```
[Expert@MyGW:0]# fwaccel tab -t drop_templates
Table drop_templates is empty
[Expert@MyGW:0]#
```

```
[Expert@MyGW:0]# fwaccel tab -t vpn_trusted_ifs
Table contents written to /var/log/messages.
[Expert@MyGW:0]#
```

```

[Expert@MyGW:0]# fwaccel tab -t profile
Table contents written to /var/log/messages.
[Expert@MyGW:0]#

[Expert@MyGW:0]# fwaccel tab -t mcast_drop_conns
Table contents written to /var/log/messages.
[Expert@MyGW:0]#

[Expert@MyGW:0]# fwaccel tab -t invalid_replay_counter
Table contents written to /var/log/messages.
[Expert@MyGW:0]#

[Expert@MyGW:0]# fwaccel tab -t ipsec_mtu_icmp
Table contents written to /var/log/messages.
[Expert@MyGW:0]#

[Expert@MyGW:0]# fwaccel tab -t gtp_tunnels
Table contents written to /var/log/messages.
[Expert@MyGW:0]#

[Expert@MyGW:0]# fwaccel tab -t gtp_apns
Table contents written to /var/log/messages.
[Expert@MyGW:0]#

[Expert@MyGW:0]# fwaccel tab -t if_by_name
Table contents written to /var/log/messages.
[Expert@MyGW:0]#

[Expert@MyGW:0]# fwaccel tab -t PMTU_table
Table PMTU_table is empty
[Expert@MyGW:0]#

[Expert@MyGW:0]# fwaccel tab -t frag_table
Table frag_table is empty
[Expert@MyGW:0]#

[Expert@MyGW:0]# fwaccel tab -t reset_table
Table reset_table is empty
[Expert@MyGW:0]#

[Expert@MyGW:0]# fwaccel tab -t dos_ip_blacklists
Table dos_ip_blacklists is not active for SecureXL device 0.
[Expert@MyGW:0]#

[Expert@MyGW:0]# fwaccel tab -t dos_pbox
Table dos_pbox is not active for SecureXL device 0.
[Expert@MyGW:0]#

[Expert@MyGW:0]# fwaccel tab -t dos_rate_matches
Table dos_rate_matches is not active for SecureXL device 0.
[Expert@MyGW:0]#

[Expert@MyGW:0]# fwaccel tab -t dos_rate_track_src
Table dos_rate_track_src is not active for SecureXL device 0.
[Expert@MyGW:0]#

[Expert@MyGW:0]# fwaccel tab -t dos_rate_track_src_svc
Table dos_rate_track_src_svc is not active for SecureXL device 0.
[Expert@MyGW:0]#

[Expert@MyGW:0]# fwaccel tab -t dos_pbox_violating_ips
Table dos_pbox_violating_ips is not active for SecureXL device 0.
[Expert@MyGW:0]#

```

# fwaccel templates

## Description

The *fwaccel templates* and *fwaccel6 templates* commands show the contents of the SecureXL templates tables:

- Accept Templates
- SecureXL Drop Templates
- Firewall Drop Templates

### Important:

- By default, all Drop Templates are disabled.  
To enable the SecureXL Drop Templates and Firewall Drop Templates:
  1. In SmartConsole, open the Security Gateway / Cluster object.
  2. In the left tree, click the **Optimizations** pane.
  3. Select **Enable drop optimization**.
  4. Click **OK**.
  5. Install the Access Control policy.
- To disable only the Firewall Drop Templates:
  1. Connect to the command line on the Security Gateway / each Cluster Member.
  2. Set the value of the kernel parameter `fw_drop_templates_enabled` to 0 (zero):
 

```
fw ctl set -f int fw_drop_templates_enabled 0
```

To enable the Firewall Drop Templates again, run:

```
fw ctl set -f int fw_drop_templates_enabled 1
```

-  **Important** - Based on the number of current templates, these commands can consume memory at very high level.

## Syntax for IPv4

```
fwaccel [-i <SecureXL ID>] templates
        [-h]
        [-c]
        [-d [{-R | -S}]
        [-m <Number of Rows>]
        [-r]
        [-R]
        [-s]
        [-S]
```

## Syntax for IPv6

```
fwaccel6 templates
    [-h]
    [-c]
    [-d [{-R | -S}]]
    [-m <Number of Rows>]
    [-r]
    [-R]
    [-s]
    [-S]
```

## Parameters

| Parameter                              | Description                                                                                                                         |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <code>-i &lt;SecureXL ID&gt;</code>    | Specifies the SecureXL instance ID (for IPv4 only).                                                                                 |
| No Parameters                          | Shows the contents of the SecureXL Accept Templates table (Table Name - <code>cphwd_tmpl</code> , Table ID - 8111).                 |
| <code>-h</code>                        | Shows the applicable built-in usage.                                                                                                |
| <code>-c</code>                        | Shows the contents of the Firewall Drop Templates table (connections).                                                              |
| <code>-d</code>                        | Shows the contents of the SecureXL Drop Templates table.                                                                            |
| <code>-d -R</code>                     | Shows statistics for the reasons for failures to create SecureXL Drop Templates.                                                    |
| <code>-d -S</code>                     | Shows statistics for the SecureXL Drop Templates.                                                                                   |
| <code>-m &lt;Number of Rows&gt;</code> | Specifies how many rows to show from the templates table.<br>Note - The command counts from the top of the table.<br>Default : 1000 |
| <code>-r</code>                        | Shows the contents of the Firewall Drop Templates table (ranges).                                                                   |
| <code>-R</code>                        | Shows the reasons for failures to create SecureXL Connections Templates.                                                            |
| <code>-s</code>                        | Shows the total number of offloaded SecureXL Connections Templates.                                                                 |
| <code>-S</code>                        | Shows statistics for the offloaded SecureXL Connections Templates.                                                                  |

## Accept Templates flags

One or more of these flags appears in the output:

| Flag | Description                                                                                                 |
|------|-------------------------------------------------------------------------------------------------------------|
| A    | Connection is accounted (SecureXL counts the number of packets and bytes).                                  |
| B    | Connection is created for a rule that contains an Identity Awareness object, or for a rule below that rule. |
| E    | Connection is created for a NAT rule that contains an Identity Awareness object.                            |
| I    | Identity Awareness (NAC) is enabled for this connection.                                                    |
| M    | Connection is created for a rule that contains a Domain object, or for a rule below that rule.              |
| N    | Connection undergoes NAT.                                                                                   |
| O    | Connection is created for a rule that contains a Dynamic object, or for a rule below that rule.             |
| P    | Connection is created for a rule that may match a Service with an explicitly configured Source port.        |
| Q    | QoS is enabled for this connection.                                                                         |
| R    | Connection is created for a rule that contains a Traceroute object, or for a rule below that rule.          |
| S    | PXL (combination of SecureXL and PSL (Passive Streaming Library)) is enabled for this connection.           |
| T    | Connection is created for a rule that contains a Time object, or for a rule below that rule.                |
| U    | Connection is unidirectional.                                                                               |
| X    | Connection is created for a NAT rule that contains a translated Dynamic object.                             |
| Z    | Connection is created for a rule that contains a Security Zone object, or for a rule below that rule.       |

## Drop Templates flags

One or more of these flags appears in the output:

| Flag | Description                                        |
|------|----------------------------------------------------|
| D    | SecureXL Drop template exists for this connection. |
| L    | Log and Drop action for this connection.           |

## Firewall Drop Templates flags

One or more of these flags appears in the output:

| Flag | Description                                                                                       |
|------|---------------------------------------------------------------------------------------------------|
| M    | Connection is created for a rule that contains a Domain object, or for a rule below that rule.    |
| O    | Connection is created for a rule that contains a Dynamic object, or for a rule below that rule.   |
| U    | Connection is created for a rule that contains a Updatable object, or for a rule below that rule. |

## Examples

### Example 1 - Default output

```
[Expert@MyGW:0]# fwaccel templates
Source          SPort Destination      DPort PR  Flags          LCT  DLY  C2S i/f S2C i/f
-----
192.168.10.20    * 192.168.10.50      80   6           0    0    0 eth5/eth1 eth1/eth5
[Expert@MyGW:0]#
```

### Example 2 - Drop Templates

```
[Expert@MyGW:0]# fwaccel templates -d
The SecureXL drop templates table is empty
[Expert@MyGW:0]#
```

### Example 3 - Summary of SecureXL Connections Templates

```
[Expert@MyGW:0]# fwaccel templates -s
Total number of templates: 1
[Expert@MyGW:0]#
```

**Example 4 - Templates statistics**

```
[Expert@MyGW:0]# fwaccel templates -S
```

```
Templates stats:
```

| Name               | Value | Name                 | Value |
|--------------------|-------|----------------------|-------|
| -----              | ----- | -----                | ----- |
| C templates        | 0     | conns from templates | 0     |
| nat templates      | 0     | conns from nat tmpl  | 0     |
| C CPASXL templates | 0     | C PSLXL templates    | 0     |
| C used templates   | 0     | cpasxl tmpl conns    | 0     |
| pslxl tmpl conns   | 0     | C conns from tmpl    | 0     |

```
[Expert@MyGW:0]#
```

# fwaccel ver

## Description

Shows this information:

- Firewall Version and Build
- Accelerator Version
- Firewall API version
- Accelerator API version

## Syntax

```
fwaccel ver
```

## Example

```
Expert@MyGW:0]# fwaccel ver
Firewall version: R82.10 - Build 123
Acceleration Device: Performance Pack
Accelerator Version 2.1
Firewall API version: 3.0NG (19/11/2015)
Accelerator API version: 3.0NG (19/11/2015)
[Expert@MyGW:0]#
```

# fw sam\_policy

## Description

Manages the Suspicious Activity Policy editor that works with these types of rules:

- Suspicious Activity Monitoring (SAM) rules.

See [sk112061: How to create and view Suspicious Activity Monitoring \(SAM\) Rules](#).

- Rate Limiting rules.

See [sk182350 - How to configure Rate Limiting rules for DoS Mitigation](#).

Also, see these commands:

- ["fw sam" on page 295](#)
- ["sam\\_alert" on page 404](#)

## Notes:

- These commands are interchangeable:
  - For IPv4: "fw sam\_policy" and "fw samp".
  - For IPv6: "fw6 sam\_policy" and "fw6 samp".
- You can run these commands in Gaia Clish, or Expert mode.
- Security Gateway stores the SAM Policy rules in the `$FWDIR/database/sam_policy.db` file.
- Security Gateway stores the SAM Policy management settings in the `$FWDIR/database/sam_policy.mng` file.

## Important:

- Configuration you make with these commands, survives reboot.
- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.
- VSNext mode and Traditional VSX mode do **not** support Suspicious Activity Monitoring (SAM) Rules. See [sk79700](#).

**Best Practice** - The SAM Policy rules consume some CPU resources on Security Gateway. Set an expiration for rules that gives you time to investigate, but does not affect performance. Keep only the required SAM Policy rules. If you confirm that an activity is risky, edit the Security Policy, educate users, or otherwise handle the risk.

## Syntax for IPv4

```
fw [-d] sam_policy  
    add <options>  
    batch  
    del <options>  
    get <options>
```

```
fw [-d] samp  
    add <options>  
    batch  
    del <options>  
    get <options>
```

## Syntax for IPv6

```
fw6 [-d] sam_policy  
    add <options>  
    batch  
    del <options>  
    get <options>
```

```
fw6 [-d] samp  
    add <options>  
    batch  
    del <options>  
    get <options>
```

## Parameters

| Parameter     | Description                                                                                                                                                                                                                                                          |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d            | <p>Runs the command in debug mode.<br/>Use only if you troubleshoot the command itself.</p> <p>★ <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p> |
| add <options> | <p>Adds one Rate Limiting rule one at a time.<br/>See <a href="#">"fw sam_policy add" on page 306</a>.</p>                                                                                                                                                           |
| batch         | <p>Adds or deletes many Rate Limiting rules at a time.<br/>See <a href="#">"fw sam_policy batch" on page 319</a>.</p>                                                                                                                                                |
| del <options> | <p>Deletes one configured Rate Limiting rule one at a time.<br/>See <a href="#">"fw sam_policy del" on page 321</a>.</p>                                                                                                                                             |
| get <options> | <p>Shows all the configured Rate Limiting rules.<br/>See <a href="#">"fw sam_policy get" on page 324</a>.</p>                                                                                                                                                        |

# fw sam\_policy add

## Description

The "fw sam\_policy add" and "fw6 sam\_policy add" commands:

- Add one Suspicious Activity Monitoring (SAM) rule at a time.
- Add one Rate Limiting rule at a time.

### Notes:

- These commands are interchangeable:
  - For IPv4: "fw sam\_policy" and "fw samp".
  - For IPv6: "fw6 sam\_policy" and "fw6 samp".
- You can run these commands in Gaia Clish, or Expert mode.
- Security Gateway stores the SAM Policy rules in the `$FWDIR/database/sam_policy.db` file.
- Security Gateway stores the SAM Policy management settings in the `$FWDIR/database/sam_policy.mng` file.

### Important:

- Configuration you make with these commands, survives reboot.
- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.
- VSNext mode and Traditional VSX mode do **not** support Suspicious Activity Monitoring (SAM) Rules. See [sk79700](#).

- ★ **Best Practice** - The SAM Policy rules consume some CPU resources on Security Gateway. Set an expiration for rules that gives you time to investigate, but does not affect performance. Keep only the required SAM Policy rules. If you confirm that an activity is risky, edit the Security Policy, educate users, or otherwise handle the risk.

## Syntax to configure a Suspicious Activity Monitoring (SAM) rule for IPv4

```
fw [-d] sam_policy add [-u] -a {d|n|b} [-l {r|a}] [-t <Timeout>]
[-f <Target>] [-n <"Rule Name">] [-c <"Rule Comment">] [-o <"Rule
Originator">] [-z "<Zone>"] ip <IP Filter Arguments>
```

## Syntax to configure a Suspicious Activity Monitoring (SAM) rule for IPv6

```
fw6 [-d] sam_policy add [-u] -a {d|n|b} [-l {r|a}] [-t <Timeout>]
[-f <Target>] [-n <"Rule Name">] [-c <"Rule Comment">] [-o <"Rule
Originator">] [-z "<Zone>"] ip <IP Filter Arguments>
```

## Syntax to configure a Rate Limiting rule for IPv4

```
fw [-d] sam_policy add [-u] -a {d|n|b} [-l {r|a}] [-t <Timeout>]
[-f <Target>] [-n <"Rule Name">] [-c <"Rule Comment">] [-o <"Rule
Originator">] [-z "<Zone>"] quota <Quota Filter Arguments>
```

## Syntax to configure a Rate Limiting rule for IPv6

```
fw6 [-d] sam_policy add [-u] -a {d|n|b} [-l {r|a}] [-t <Timeout>]
[-f <Target>] [-n <"Rule Name">] [-c <"Rule Comment">] [-o <"Rule
Originator">] [-z "<Zone>"] quota <Quota Filter Arguments>
```

## Parameters

| Parameter      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d             | Runs the command in debug mode.<br>Use only if you troubleshoot the command itself.<br> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.                                                                                                                                                                                                                                                |
| -u             | Optional.<br>Specifies that the rule category is User-defined.<br>Default rule category is Auto.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| -a {d   n   b} | Mandatory.<br>Specifies the rule action if the traffic matches the rule conditions: <ul style="list-style-type: none"> <li>■ d - Drop the connection.</li> <li>■ n - Notify (generate a log) about the connection and let it through.</li> <li>■ b - Bypass the connection - let it through without checking it against the policy rules.</li> </ul> <b>Note</b> - Rules with action set to <i>Bypass</i> cannot have a log or limit specification. Bypassed packets and connections do not count towards overall number of packets and connection for limit enforcement of type ratio. |
| -l {r   a}     | Optional.<br>Specifies which type of log to generate for this rule for all traffic that matches: <ul style="list-style-type: none"> <li>■ -r - Generate a regular log</li> <li>■ -a - Generate an alert log</li> </ul>                                                                                                                                                                                                                                                                                                                                                                  |

| Parameter                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -t<br><i>&lt;Timeout&gt;</i>       | Optional.<br>Specifies the time period (in seconds), during which the rule will be enforced.<br>Default timeout is indefinite.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| -f <i>&lt;Target&gt;</i>           | Optional.<br>Specifies the target Security Gateways, on which to enforce the Rate Limiting rule.<br><i>&lt;Target&gt;</i> can be one of these: <ul style="list-style-type: none"> <li>■ <b>all</b> - This is the default option. Specifies that the rule should be enforced on all managed Security Gateways.</li> <li>■ <b>Name of the Security Gateway or Cluster object</b> - Specifies that the rule should be enforced only on this Security Gateway or Cluster object (the object name must be as defined in the SmartConsole).</li> <li>■ <b>Name of the Group object</b> - Specifies that the rule should be enforced on all Security Gateways that are members of this Group object (the object name must be as defined in the SmartConsole).</li> </ul> |
| -n " <i>&lt;Rule Name&gt;</i> "    | Optional.<br>Specifies the name (label) for this rule.<br><b>Notes:</b> <ul style="list-style-type: none"> <li>■ You must enclose this string in double quotes.</li> <li>■ The length of this string is limited to 128 characters.</li> <li>■ Before each space or a backslash character in this string, you must write a backslash (\) character. Example:               <div style="border: 1px solid black; padding: 5px; margin-top: 10px;">                 "This\ is\ a\ rule\ name\ with\ a\ backslash\ \\"               </div> </li> </ul>                                                                                                                                                                                                               |
| -c " <i>&lt;Rule Comment&gt;</i> " | Optional.<br>Specifies the comment for this rule.<br><b>Notes:</b> <ul style="list-style-type: none"> <li>■ You must enclose this string in double quotes.</li> <li>■ The length of this string is limited to 128 characters.</li> <li>■ Before each space or a backslash character in this string, you must write a backslash (\) character. | <code>quota</code><br><code>&lt;Quota</code><br><code>Filter</code><br><code>Arguments&gt;</code> | <p>Mandatory (use this <code>quota</code> parameter, or the <code>ip</code> parameter).<br/> Configures the <i>Rate Limiting</i> rule.<br/> Specifies the Quota Filter Arguments for the Rate Limiting rule (see the explanations below):</p> <ul style="list-style-type: none"> <li>■ <code>[flush true]</code></li> <li>■ <code>[source-negated {true   false}] source &lt;Source&gt;</code></li> <li>■ <code>[destination-negated {true   false}] destination &lt;Destination&gt;</code></li> <li>■ <code>[service-negated {true   false}] service &lt;Protocol and Port numbers&gt;</code></li> <li>■ <code>[&lt;Limit1 Name&gt; &lt;Limit1 Value&gt;] [&lt;Limit2 Name&gt; &lt;Limit2 Value&gt;] ... [&lt;LimitN Name&gt; &lt;LimitN Value&gt;]</code></li> <li>■ <code>[track &lt;Track&gt;]</code></li> </ul> <p> <b>Important:</b></p> <ul style="list-style-type: none"> <li>■ The Quota rules are not applied immediately to the Security Gateway. They are only registered in the Suspicious Activity Monitoring (SAM) policy database. To apply all the rules from the SAM policy database immediately, add "flush true" in the <code>fw sam_policy add</code> command syntax.</li> <li>■ Explanation:<br/> For new connections rate (and for any rate limiting in general), when a rule's limit is violated, the Security Gateway also drops all packets that match the rule.<br/> The Security Gateway computes new connection rates on a per-second basis.<br/> At the start of the 1-second timer, the Security Gateway allows all packets, including packets for existing connections.<br/> If, at some point, during that 1 second period, there are too many new connections, then the Security Gateway blocks all remaining packets for the remainder of that 1-second interval.<br/> At the start of the next 1-second interval, the counters are reset, and the process starts over - the Security Gateway allows packets to pass again up to the point, where the rule's limit is violated.</li> </ul> |

## Explanation for the *IP Filter Arguments* syntax for Suspicious Activity Monitoring (SAM) rules

| Argument              | Description                                                                                  |
|-----------------------|----------------------------------------------------------------------------------------------|
| -C                    | Specifies that open connections should be closed.                                            |
| -s <Source IP>        | Specifies the Source IP address.                                                             |
| -m <Source Mask>      | Specifies the Source subnet mask (in dotted decimal format - x.y.z.w).                       |
| -d <Destination IP>   | Specifies the Destination IP address.                                                        |
| -M <Destination Mask> | Specifies the Destination subnet mask (in dotted decimal format - x.y.z.w).                  |
| -p <Port>             | Specifies the port number (see <a href="#">IANA Service Name and Port Number Registry</a> ). |
| -r <Protocol>         | Specifies the protocol number (see <a href="#">IANA Protocol Numbers</a> ).                  |

Explanation for the *Quota Filter Arguments* syntax for Rate Limiting rules

| Argument                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Examples

### Example 1 - Rate Limiting rule with a range

```
fw sam_policy add -a d -l r -t 3600 quota service any source range:172.16.7.11-172.16.7.13 new-conn-rate 5 flush true
```

#### Explanations:

- This rule drops packets for all connections (`-a d`) that exceed the quota set by this rule, including packets for existing connections.
- This rule logs packets (`-l r`) that exceed the quota set by this rule.
- This rule will expire in 3600 seconds (`-t 3600`).
- This rule limits the rate of creation of new connections to 5 connections per second (`new-conn-rate 5`) for any traffic (`service any`) from the source IP addresses in the range 172.16.7.11 - 172.16.7.13 (`source range:172.16.7.11-172.16.7.13`).

**Note** - The limit of the total number of log entries per second is configured with the *fwaccel dos config set -n <rate>* command.

- This rule will be compiled and loaded on the SecureXL, together with other rules in the Suspicious Activity Monitoring (SAM) policy database immediately, because this rule includes the "flush true" parameter.

## Example 2 - Rate Limiting rule with a service specification

```
fw sam_policy add -a n -l r quota service 1,50-51,6/443,17/53 service-negated true source cc:QQ byte-rate 0
```

### Explanations:

- This rule logs and lets through all packets (`-a n`) that exceed the quota set by this rule.
- This rule does not expire (the `timeout` parameter is not specified). To cancel it, you must delete it explicitly.
- This rule applies to all packets except (`service-negated true`) the packets with IP protocol number 1, 50-51, 6 port 443 and 17 port 53 (`service 1,50-51,6/443,17/53`).
- This rule applies to all packets from source IP addresses that are assigned to the country with specified country code (`cc:QQ`).
- This rule does not let any traffic through (`byte-rate 0`) except the packets with IP protocol number 1, 50-51, 6 port 443 and 17 port 53.
- This rule will not be compiled and installed on the SecureXL immediately, because it does not include the "`flush true`" parameter.

## Example 3 - Rate Limiting rule with ASN

```
fw sam_policy -a d quota source asn:AS64500,cidr:[::FFFF:C0A8:1100]/120 service any pkt-rate 0
```

### Explanations:

- This rule drops (`-a d`) all packets that match this rule.
- This rule does not expire (the `timeout` parameter is not specified). To cancel it, you must delete it explicitly.
- This rule applies to packets from the Autonomous System number 64500 (`asn:AS64500`).
- This rule applies to packets from source IPv6 addresses FFFF:C0A8:1100/120 (`cidr:[::FFFF:C0A8:1100]/120`).
- This rule applies to all traffic (`service any`).
- This rule does not let any traffic through (`pkt-rate 0`).
- This rule will not be compiled and installed on the SecureXL immediately, because it does not include the "`flush true`" parameter.

## Example 4 - Rate Limiting rule with an Allow List

```
fw sam_policy add -a b quota source range:172.16.8.17-172.16.9.121 service 6/80
```

### Explanations:

- This rule bypasses (`-a b`) all packets that match this rule.

**Note** - The Access Control Policy and other types of security policy rules still apply.

- This rule does not expire (the `timeout` parameter is not specified). To cancel it, you must delete it explicitly.
- This rule applies to packets from the source IP addresses in the range 172.16.8.17 - 172.16.9.121 (`range:172.16.8.17-172.16.9.121`).
- This rule applies to packets sent to TCP port 80 (`service 6/80`).
- This rule will not be compiled and installed on the SecureXL immediately, because it does not include the "`flush true`" parameter.

### Example 5 - Rate Limiting rule with tracking

```
fw sam_policy add -a d quota service any source-negated true source cc:QQ concurrent-conns-ratio 655 track source
```

#### Explanations:

- This rule drops (`-a d`) all packets that match this rule.
- This rule does not log any packets (the `-l r` parameter is not specified).
- This rule does not expire (the `timeout` parameter is not specified). To cancel it, you must delete it explicitly.
- This rule applies to all traffic (`service any`).
- This rule applies to all sources except (`source-negated true`) the source IP addresses that are assigned to the country with specified country code (`cc:QQ`).
- This rule limits the maximum number of concurrent active connections to  $655/65536 \approx 1\%$  (`concurrent-conns-ratio 655`) for any traffic (`service any`) except (`source-negated true`) the connections from the source IP addresses that are assigned to the country with specified country code (`cc:QQ`).
- This rule counts connections, packets, and bytes for traffic only from sources that match this rule, and not cumulatively for this rule.
- This rule will not be compiled and installed on the SecureXL immediately, because it does not include the "`flush true`" parameter.

# fw sam\_policy batch

## Description

The "fw sam\_policy batch" and "fw6 sam\_policy batch" commands:

- Add and delete many Suspicious Activity Monitoring (SAM) rules at a time.
- Add and delete many Rate Limiting rules at a time.

### Notes:

- These commands are interchangeable:
  - For IPv4: "fw sam\_policy" and "fw samp".
  - For IPv6: "fw6 sam\_policy" and "fw6 samp".
- You can run these commands in Gaia Clish, or Expert mode.
- Security Gateway stores the SAM Policy rules in the `$FWDIR/database/sam_policy.db` file.
- Security Gateway stores the SAM Policy management settings in the `$FWDIR/database/sam_policy.mng` file.

### Important:

- Configuration you make with these commands, survives reboot.
- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.
- VSNext mode and Traditional VSX mode do **not** support Suspicious Activity Monitoring (SAM) Rules. See [sk79700](#).

- ★ **Best Practice** - The SAM Policy rules consume some CPU resources on Security Gateway. Set an expiration for rules that gives you time to investigate, but does not affect performance. Keep only the required SAM Policy rules. If you confirm that an activity is risky, edit the Security Policy, educate users, or otherwise handle the risk.

## Procedure

### 1. Start the batch mode

- For IPv4, run:

```
fw sam_policy batch << EOF
```

- For IPv6, run:

```
fw6 sam_policy batch << EOF
```

## 2. Enter the applicable commands

- Enter one "add" or "del" command on each line, on as many lines as necessary.

Start each line with only "add" or "del" parameter (not with "fw samp").

- Use the same set of parameters and values as described in these commands:
  - fw sam\_policy add
  - fw sam\_policy del
- Terminate each line with a Return (ASCII 10 - Line Feed) character (press Enter).

## 3. End the batch mode

Type EOF and press Enter.

### Example of a Rate Limiting rule for IPv4

```
[Expert@HostName]# fw samp batch <<EOF
add -a d -l r -t 3600 -c "Limit\ conn\ rate\ to\ 5\ conn/sec from\ these\ sources" quota service
any source range:172.16.7.13-172.16.7.13 new-conn-rate 5

del <501f6ef0,00000000,cb38a8c0,0a0afffe>

add -a b quota source range:172.16.8.17-172.16.9.121 service 6/80

EOF
[Expert@HostName]#
```

# fw sam\_policy del

## Description

The "fw sam\_policy del" and "fw6 sam\_policy del" commands:

- Delete one configured Suspicious Activity Monitoring (SAM) rule at a time.
- Delete one configured Rate Limiting rule at a time.

### Notes:

- These commands are interchangeable:
  - For IPv4: "fw sam\_policy" and "fw samp".
  - For IPv6: "fw6 sam\_policy" and "fw6 samp".
- You can run these commands in Gaia Clish, or Expert mode.
- Security Gateway stores the SAM Policy rules in the `$FWDIR/database/sam_policy.db` file.
- Security Gateway stores the SAM Policy management settings in the `$FWDIR/database/sam_policy.mng` file.

### Important:

- Configuration you make with these commands, survives reboot.
- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.
- VSNext mode and Traditional VSX mode do **not** support Suspicious Activity Monitoring (SAM) Rules. See [sk79700](#).

- ★ **Best Practice** - The SAM Policy rules consume some CPU resources on Security Gateway. Set an expiration for rules that gives you time to investigate, but does not affect performance. Keep only the required SAM Policy rules. If you confirm that an activity is risky, edit the Security Policy, educate users, or otherwise handle the risk.

## Syntax for IPv4

```
fw [-d] sam_policy del '<Rule UID>'
```

## Syntax for IPv6

```
fw6 [-d] sam_policy del '<Rule UID>'
```

## Parameters

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                         |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d           | Runs the command in debug mode.<br>Use only if you troubleshoot the command itself.<br> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.            |
| '<Rule UID>' | Specifies the UID of the rule you wish to delete.<br> <b>Important:</b> <ul style="list-style-type: none"> <li>■ The quote marks and angle brackets ('&lt;...&gt;') are mandatory.</li> <li>■ To see the Rule UID, run the "fw sam_policy get" command.</li> </ul> |

## Procedure

### 1. List all the existing rules in the Suspicious Activity Monitoring policy database

List all the existing rules in the Suspicious Activity Monitoring policy database.

- For IPv4, run:

```
fw sam_policy get
```

- For IPv6, run:

```
fw6 sam_policy get
```

The rules show in this format:

```
operation=add uid=<Value1,Value2,Value3,Value4> target=...
timeout=... action=... log= ... name= ... comment=...
originator= ... src_ip_addr=... req_tpe=...
```

Example for IPv4:

```
operation=add uid=<5ac3965f,00000000,3403a8c0,0000264a>
target=all timeout=300 action=notify log=log name=Test\ Rule
comment=Notify\ about\ traffic\ from\ 1.1.1.1
originator=John\ Doe src_ip_addr=1.1.1.1 req_tpe=ip
```

## 2. Delete a rule from the list by its UID

- For IPv4, run:

```
fw [-d] sam_policy del '<Rule UID>'
```

- For IPv6, run:

```
fw6 [-d] sam_policy del '<Rule UID>'
```

Example for IPv4:

```
fw samp del '<5ac3965f,00000000,3403a8c0,0000264a>'
```

## 3. Add the flush-only rule

- For IPv4, run:

```
fw samp add -t 2 quota flush true
```

- For IPv6, run:

```
fw6 samp add -t 2 quota flush true
```

Explanation:

The "fw samp del" and "fw6 samp del" commands only remove a rule from the persistent database. The Security Gateway continues to enforce the deleted rule until the next time you compiled and load a policy. To force the rule deletion immediately, you must enter a flush-only rule right after the "fw samp del" and "fw6 samp del" command. This flush-only rule immediately deletes the rule you specified in the previous step, and times out in 2 seconds.

- ★ **Best Practice** - Specify a short timeout period for the flush-only rules. This prevents accumulation of rules that are obsolete in the database.

# fw sam\_policy get

## Description

The "fw sam\_policy get" and "fw6 sam\_policy get" commands:

- Show all the configured Suspicious Activity Monitoring (SAM) rules.
- Show all the configured Rate Limiting rules.

## Notes:

- These commands are interchangeable:
  - For IPv4: "fw sam\_policy" and "fw samp".
  - For IPv6: "fw6 sam\_policy" and "fw6 samp".
- You can run these commands in Gaia Clish, or Expert mode.
- Security Gateway stores the SAM Policy rules in the `$FWDIR/database/sam_policy.db` file.
- Security Gateway stores the SAM Policy management settings in the `$FWDIR/database/sam_policy.mng` file.

## Important:

- Configuration you make with these commands, survives reboot.
- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.
- VSNext mode and Traditional VSX mode do **not** support Suspicious Activity Monitoring (SAM) Rules. See [sk79700](#).

- ★ **Best Practice** - The SAM Policy rules consume some CPU resources on Security Gateway. Set an expiration for rules that gives you time to investigate, but does not affect performance. Keep only the required SAM Policy rules. If you confirm that an activity is risky, edit the Security Policy, educate users, or otherwise handle the risk.

## Syntax for IPv4

```
fw [-d] sam_policy get [-l] [-u '<Rule UID>'] [-k '<Key>' -t
<Type> [{-v '<Value>'}] [-n]]
```

## Syntax for IPv6

```
fw6 [-d] sam_policy get [-l] [-u '<Rule UID>'] [-k '<Key>' -t
<Type> [{-v '<Value>'}] [-n]]
```

## Parameters

**Note** - All these parameters are optional.

| Parameter       | Description                                                                                                                                                                                                                                                                                                                              |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d              | Runs the command in debug mode.<br>Use only if you troubleshoot the command itself.<br> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session. |
| -l              | Controls how to print the rules: <ul style="list-style-type: none"> <li>■ In the default format (without "-l"), the output shows each rule on a separate line.</li> <li>■ In the list format (with "-l"), the output shows each parameter of a rule on a separate line.</li> <li>■ See the "fw sam_policy add" command.</li> </ul>       |
| -u '<Rule UID>' | Prints the rule specified by its Rule UID or its zero-based rule index.<br>The quote marks and angle brackets ('<...>') are mandatory.                                                                                                                                                                                                   |
| -k '<Key>'      | Prints the rules with the specified predicate key.<br>The quote marks are mandatory.                                                                                                                                                                                                                                                     |
| -t <Type>       | Prints the rules with the specified predicate type.<br>For Rate Limiting rules, you must always use "-t in".                                                                                                                                                                                                                             |
| +{-v '<Value>'} | Prints the rules with the specified predicate values.<br>The quote marks are mandatory.                                                                                                                                                                                                                                                  |
| -n              | Negates the condition specified by these predicate parameters: <ul style="list-style-type: none"> <li>■ -k</li> <li>■ -t</li> <li>■ +-v</li> </ul>                                                                                                                                                                                       |

## Examples

### Example 1 - Output in the default format

```
[Expert@HostName:0]# fw samp get

operation=add uid=<5ac3965f,00000000,3403a8c0,0000264a> target=all timeout=300 action=notify
log=log name=Test\ Rule comment=Notify\ about\ traffic\ from\ 1.1.1.1 originator=John\ Doe
src_ip_addr=1.1.1.1 req_tpe=ip
```

**Example 2 - Output in the list format**

```
[Expert@HostName:0]# fw samp get -l
uid
<5ac3965f,00000000,3403a8c0,0000264a>
target
all
timeout
2147483647
action
notify
log
log
name
Test\ Rule
comment
Notify\ about\ traffic\ from\ 1.1.1.1
originator
John\ Doe
src_ip_addr
1.1.1.1
req_type
ip
```

**Example 3 - Printing a rule by its Rule UID**

```
[Expert@HostName:0]# fw samp get -u '<5ac3965f,00000000,3403a8c0,0000264a>'
0
operation=add uid=<5ac3965f,00000000,3403a8c0,0000264a> target=all timeout=300 action=notify
log=log name=Test\ Rule comment=Notify\ about\ traffic\ from\ 1.1.1.1 originator=John\ Doe
src_ip_addr=1.1.1.1 req_tpe=ip
```

#### Example 4 - Printing rules that match the specified filters

```

[Expert@HostName:0]# fw samp get
no corresponding SAM policy requests
[Expert@HostName:0]#
[Expert@HostName:0]# fw samp add -a d -l r -t 3600 quota service any source
range:172.16.7.11-172.16.7.13 new-conn-rate 5 flush true

# The /proc/ppk/ and /proc/ppk6/ entries

## Description

SecureXL supports Linux **/proc** entries. The read-only entries in the **/proc/ppk/** and **/proc/ppk6/** contain various data about SecureXL.

## Syntax for IPv4

```
[Expert@MyGW:0]# ls -lR /proc/ppk/
```

```
[Expert@MyGW:0]# cat /proc/ppk/<Name of File>
```

```
[Expert@MyGW:0]# cat /proc/ppk/<SecureXL Instance ID>/<Name of File>
```

## Syntax for IPv6

```
[Expert@MyGW:0]# ls -lR /proc/ppk6/
```

```
[Expert@MyGW:0]# cat /proc/ppk6/<Name of File>
```

```
[Expert@MyGW:0]# cat /proc/ppk6/<SecureXL Instance ID>/<Name of File>
```

## Files

| File     | Description                                                                                                                        |
|----------|------------------------------------------------------------------------------------------------------------------------------------|
| affinity | Contains status and the thresholds for SecureXL New Affinity mechanism.<br>See <a href="#">"/proc/ppk/affinity" on page 1667</a> . |
| conf     | Contains the SecureXL configuration and basic statistics.<br>See <a href="#">"/proc/ppk/conf" on page 1668</a> .                   |

| stats             | Contains the IRQ numbers and names of interfaces the SecureXL uses.<br>See <a href="#">"/proc/ppk/stats" on page 1686</a> .                                                 |
| viol_statistics   | Contains SecureXL statistics for violations - packets SecureXL forwarded (F2F) to the Firewall.<br>See <a href="#">"/proc/ppk/viol_statistics" on page 1687</a> .           |

# /proc/ppk/affinity

## Description

Contains the number of accelerated packets per second and rate of encrypted bytes.

## Syntax for IPv4

```
[Expert@MyGW:0]# ls -lR /proc/ppk/
```

```
[Expert@MyGW:0]# cat /proc/ppk/affinity
```

## Syntax for IPv6

```
[Expert@MyGW:0]# ls -lR /proc/ppk6/
```

```
[Expert@MyGW:0]# cat /proc/ppk6/affinity
```

## Example for IPv4

```
[Expert@MyGW:0]# cat /proc/ppk/affinity
Current accelerated PPS      : 0
Current enc. bytes rate     : 0
[Expert@MyGW:0]#
```

# /proc/ppk/conf

## Description

Contains the SecureXL configuration and basic statistics.

## Syntax for IPv4

```
[Expert@MyGW:0]# ls -lR /proc/ppk/
[Expert@MyGW:0]# cat /proc/ppk/conf
[Expert@MyGW:0]# cat /proc/ppk/<SecureXL Instance ID>/conf
```

## Syntax for IPv6

```
[Expert@MyGW:0]# ls -lR /proc/ppk6/
[Expert@MyGW:0]# cat /proc/ppk6/conf
[Expert@MyGW:0]# cat /proc/ppk6/<SecureXL Instance ID>/conf
```

## Example for IPv4

```
[Expert@MyGW:0]# cat /proc/ppk/conf
Flags : 0x00000592

# /proc/ppk/conns

## Description

Contains the list of the SecureXL connections.

 **Important** - This file is for future use. Refer to the ["fwaccel conns" on page 1466](#) command.

## Syntax for IPv4

```
[Expert@MyGW:0]# ls -lR /proc/ppk/
```

```
[Expert@MyGW:0]# cat /proc/ppk/conns
```

```
[Expert@MyGW:0]# cat /proc/ppk/<SecureXL Instance ID>/conns
```

## Syntax for IPv6

```
[Expert@MyGW:0]# ls -lR /proc/ppk6/
```

```
[Expert@MyGW:0]# cat /proc/ppk6/conns
```

```
[Expert@MyGW:0]# cat /proc/ppk6/<SecureXL Instance ID>/conns
```

# /proc/ppk/cpls

## Description

Contains SecureXL configuration for ClusterXL Load Sharing (CPLS).

**Important** - This file is for future use. Refer to the "fwaccel cfg -h" command (see ["fwaccel cfg" on page 1462](#)).

## Syntax for IPv4

```
[Expert@MyGW:0]# ls -lR /proc/ppk/
```

```
[Expert@MyGW:0]# cat /proc/ppk/cpls
```

## Syntax for IPv6

```
[Expert@MyGW:0]# ls -lR /proc/ppk6/
```

```
[Expert@MyGW:0]# cat /proc/ppk6/cpls
```

## Example for IPv4

```
[Expert@MyGW:0]# cat /proc/ppk/cpls

# /proc/ppk/drop\_statistics

## Description

Contains SecureXL statistics for dropped packets.

 **Note** - This is the same information that the "fwaccel stats -d" command shows (see ["fwaccel stats" on page 1583](#)).

## Syntax for IPv4

```
[Expert@MyGW:0]# ls -lR /proc/ppk/
[Expert@MyGW:0]# cat /proc/ppk/drop_statistics
[Expert@MyGW:0]# cat /proc/ppk/<SecureXL Instance ID>/drop_
statistics
```

## Syntax for IPv6

```
[Expert@MyGW:0]# ls -lR /proc/ppk6/
[Expert@MyGW:0]# cat /proc/ppk6/drop_statistics
[Expert@MyGW:0]# cat /proc/ppk6/<SecureXL Instance ID>/drop_
statistics
```

## Example for IPv4

```
[Expert@MyGW:0]# cat /proc/ppk/drop_statistics

[Expert@MyGW:0]#
```

## /proc/ppk/ifs

### Description

Contains the list of interfaces that SecureXL uses.

### Syntax for IPv4

```
[Expert@MyGW:0]# ls -lR /proc/ppk/
```

```
[Expert@MyGW:0]# cat /proc/ppk/ifs
```

### Syntax for IPv6

```
[Expert@MyGW:0]# ls -lR /proc/ppk6/
```

```
[Expert@MyGW:0]# cat /proc/ppk6/ifs
```

### Example for IPv4

```
[Expert@MyGW:0]# cat /proc/ppk/ifs
No | Interface | Address          | IRQ | F   | SIM F | Dev                  | Output Func

### Explanation about the configuration flags in the "F" and "SIM F" columns

The "F" column shows the internal configuration flags that Firewall set on these interfaces.

The "SIM F" column shows the internal configuration flags that SecureXL set on these interfaces.

| Flag  | Description                                                                                                                                                                                                                                                                                                                                                   |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0x001 | If this flag is set, the SecureXL drops the packet at the end of the inbound inspection, if the packet is a "cut-through" packet.<br>In outbound, SecureXL forwards all the packets to the network.                                                                                                                                                           |
| 0x002 | If this flag is set, the SecureXL sends an applicable notification when a TCP state change occurs (connection is established or torn down).                                                                                                                                                                                                                   |
| 0x004 | If this flag is set, the SecureXL it sets the UDP header's checksum field correctly when the SecureXL encapsulates an encrypted packet (UDP encapsulation).<br>If this flag is not set, SecureXL sets the UDP header's checksum field to zero. It is safe to ignore this flag, if it is set to 0 (SecureXL continues to calculate the UDP packet's checksum). |
| 0x008 | If this flag is set, the SecureXL does not create new connections that match a template, and SecureXL drops the packet that matches the template, when the number of entries in the Connections Table reaches the specified limit.<br>If this flag is not set, the SecureXL forwards the packet to the Firewall.                                              |

| Flag   | Description                                                                                                                                                                                                                               |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0x010  | If this flag is set, the SecureXL forwards fragments to the Firewall.                                                                                                                                                                     |
| 0x020  | If this flag is set, the SecureXL does not create connections from TCP templates anymore.<br>The Firewall offloads connections to SecureXL when necessary.<br>This flag only disables the creation of TCP templates.                      |
| 0x040  | If this flag is set, the SecureXL notifies the Firewall at intervals, so it refreshes the accelerated connections in the Firewall kernel tables.                                                                                          |
| 0x080  | If this flag is set, the SecureXL does not create connections from non-TCP templates anymore.<br>The Firewall offloads connections to SecureXL when necessary.<br>This flag only disables the creation of non-TCP templates.              |
| 0x100  | If this flag is set, the SecureXL allows sequence verification violations for connections that did not complete the TCP 3-way handshake process.<br>If this flag is not set, SecureXL must forward the violating packets to the Firewall. |
| 0x200  | If this flag is set, the SecureXL allows sequence verification violations for connections that completed the TCP 3-way handshake process.<br>If this flag is not set, SecureXL must forward the violating packets to the Firewall.        |
| 0x400  | If this flag is set, the SecureXL forwards TCP [RST] packets to the Firewall.                                                                                                                                                             |
| 0x0001 | If this flag is set, the SecureXL notifies the Firewall about HitCount data.                                                                                                                                                              |
| 0x0002 | If this flag is set, the VSX Virtual System works as a junction, rather than a regular Virtual System (only the local Virtual System flag is applicable).                                                                                 |
| 0x0004 | If this flag is set, the SecureXL disables the reply counter of inbound encrypted traffic.<br>At a result, SecureXL kernel module works in the same way as the VPN kernel module.                                                         |
| 0x0008 | If this flag is set, the SecureXL enables the MSS Clamping.<br>Refer to the kernel parameters "fw_clamp_tcp_mss" and "fw_clamp_vpn_mss" in <a href="#">sk101219</a> .                                                                     |
| 0x0010 | If this flag is set, the SecureXL disables the "No Match Ranges" (NMR) Templates.                                                                                                                                                         |

| Flag   | Description                                                                                                                                                                                                                                                                                           |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0x0020 | If this flag is set, the SecureXL disables the "No Match Time" (NMT) Templates.                                                                                                                                                                                                                       |
| 0x0040 | If this flag is set, the SecureXL does not send Drop Templates notifications about dropped packets to the Firewall (to update the drop counters). For example, if you set the value of the kernel parameter "activate_optimize_drops_support_now" to 1, it disables the Drop Templates notifications. |
| 0x0080 | If this flag is set, the SecureXL enables the MultiCore support for IPSec VPN (see <a href="#">sk118097</a> ).                                                                                                                                                                                        |
| 0x0100 | If this flag is set, the SecureXL enables the support for CoreXL Dynamic Dispatcher (see <a href="#">sk105261</a> ).                                                                                                                                                                                  |
| 0x0800 | If this flag is set, the SecureXL does not enforce the Path MTU Discovery for IP multicast packets.                                                                                                                                                                                                   |
| 0x1000 | If this flag is set, the SecureXL disables the SIM "drop_templates" feature.                                                                                                                                                                                                                          |
| 0x2000 | If this flag is set, it indicates that an administrator enabled the Link Selection Load Sharing feature.                                                                                                                                                                                              |
| 0x4000 | If this flag is set, the SecureXL disables the asynchronous notification feature.                                                                                                                                                                                                                     |
| 0x8000 | If this flag is set, it indicates that the capacity of the Firewall Connections Table is unlimited.                                                                                                                                                                                                   |

Examples:

| Value      | Description                                                                                                                                                                                          |

# /proc/ppk/mcast\_statistics

## Description

Contains SecureXL statistics for multicast traffic.

 **Note** - This is the same information that the "fwaccel stats -m" command shows (see "[fwaccel stats](#)" on page 1583).

## Syntax for IPv4

|                                                                        |
|------------------------------------------------------------------------|
| [Expert@MyGW:0]# ls -lR /proc/ppk/                                     |
| [Expert@MyGW:0]# cat /proc/ppk/mcast_statistics                        |
| [Expert@MyGW:0]# cat /proc/ppk/<SecureXL Instance ID>/mcast_statistics |

## Syntax for IPv6

|                                                                         |
|-------------------------------------------------------------------------|
| [Expert@MyGW:0]# ls -lR /proc/ppk6/                                     |
| [Expert@MyGW:0]# cat /proc/ppk6/mcast_statistics                        |
| [Expert@MyGW:0]# cat /proc/ppk6/<SecureXL Instance ID>/mcast_statistics |

## Example for IPv4

|                                                 |       |                    |       |
|-------------------------------------------------|-------|--------------------|-------|
| [Expert@MyGW:0]# cat /proc/ppk/mcast_statistics |       |                    |       |
| Name                                            | Value | Name               | Value |
| -----                                           | ----- | -----              | ----- |
| in packets                                      | 10100 | out packets        | 0     |
| if restricted                                   | 0     | conns with down if | 0     |
| f2f packets                                     | 0     | f2f bytes          | 0     |
| dropped packets                                 | 0     | dropped bytes      | 0     |
| accel packets                                   | 0     | accel bytes        | 0     |
| mcast conns                                     | 0     |                    |       |
| [Expert@MyGW:0]#                                |       |                    |       |

# /proc/ppk/nac

## Description

Contains SecureXL statistics for Identity Awareness Network Access Control (NAC) traffic.

 **Note** - This is the same information that the "fwaccel stats -n" command shows (see "[fwaccel stats](#)" on page 1583).

## Syntax for IPv4

|                                                           |
|-----------------------------------------------------------|
| [Expert@MyGW:0]# ls -lR /proc/ppk/                        |
| [Expert@MyGW:0]# cat /proc/ppk/nac                        |
| [Expert@MyGW:0]# cat /proc/ppk/<SecureXL Instance ID>/nac |

## Syntax for IPv6

|                                                            |
|------------------------------------------------------------|
| [Expert@MyGW:0]# ls -lR /proc/ppk6/                        |
| [Expert@MyGW:0]# cat /proc/ppk6/nac                        |
| [Expert@MyGW:0]# cat /proc/ppk6/<SecureXL Instance ID>/nac |

## Example for IPv4

|                                    |       |                    |       |
|------------------------------------|-------|--------------------|-------|
| [Expert@MyGW:0]# cat /proc/ppk/nac |       |                    |       |
| Name                               | Value | Name               | Value |
| -----                              | ----- | -----              | ----- |
| NAC packets                        | 0     | NAC bytes          | 0     |
| NAC connections                    | 0     | compliance failure | 0     |
| [Expert@MyGW:0]#                   |       |                    |       |

## /proc/ppk/notify\_statistics

### Description

Contains SecureXL statistics for notifications SecureXL sent to Firewall about accelerated connections.

### Syntax for IPv4

```
[Expert@MyGW:0]# ls -lR /proc/ppk/
```

```
[Expert@MyGW:0]# cat /proc/ppk/notify_statistics
```

```
[Expert@MyGW:0]# cat /proc/ppk/<SecureXL Instance ID>/notify_
statistics
```

### Syntax for IPv6

```
[Expert@MyGW:0]# ls -lR /proc/ppk6/
```

```
[Expert@MyGW:0]# cat /proc/ppk6/notify_statistics
```

```
[Expert@MyGW:0]# cat /proc/ppk6/<SecureXL Instance ID>/notify_
statistics
```

## Example for IPv4

```
[Expert@MyGW:0]# cat /proc/ppk/notify_statistics
```

| Notification           | Packets | Notification          | Packets |
|------------------------|---------|-----------------------|---------|
| ntSAAboutToExpire      | 0       | ntSAExpired           | 0       |

| ntPrintGetParam        | 0       |                       |         |

```
[Expert@MyGW:0]#
```

# /proc/ppk/profile\_cpu\_stat

## Description

This file is for Check Point use only.

Contains IDs of the CPU cores and status of Traffic Profiling:

- The first column shows the IDs of the CPU cores.
- The second column shows the status of Traffic Profiling for the applicable CPU core.

## Syntax for IPv4

```
[Expert@MyGW:0]# ls -lR /proc/ppk/
[Expert@MyGW:0]# cat /proc/ppk/profile_cpu_stat
[Expert@MyGW:0]# cat /proc/ppk/<SecureXL Instance ID>/profile_cpu_stat
```

## Syntax for IPv6

```
[Expert@MyGW:0]# ls -lR /proc/ppk6/
[Expert@MyGW:0]# cat /proc/ppk6/profile_cpu_stat
[Expert@MyGW:0]# cat /proc/ppk6/<SecureXL Instance ID>/profile_cpu_stat
```

## Example for IPv4 from a Security Gateway with 4 CPU cores

```
[Expert@MyGW:0]# cat /proc/ppk/profile_cpu_stat
0 0
1 0
2 0
3 0
[Expert@MyGW:0]#
```

## /proc/ppk/rlc

### Description

Contains SecureXL statistics for drops due to Rate Limiting for DoS Mitigation.

### Syntax for IPv4

```
[Expert@MyGW:0]# ls -lR /proc/ppk/
```

```
[Expert@MyGW:0]# cat /proc/ppk/rlc
```

### Syntax for IPv6

```
[Expert@MyGW:0]# ls -lR /proc/ppk6/
```

```
[Expert@MyGW:0]# cat /proc/ppk6/rlc
```

### Example for IPv4

```
[Expert@MyGW:0]# cat /proc/ppk/rlc
Total drop packets : 0
Total drop bytes : 0
[Expert@MyGW:0]#
```

## /proc/ppk/statistics

### Description

Contains SecureXL overall statistics.

To see these statistics in a better way, run the ["fwaccel stats" on page 1583](#) command.

### Syntax for IPv4

```
[Expert@MyGW:0]# ls -lR /proc/ppk/
```

```
[Expert@MyGW:0]# cat /proc/ppk/statistics
```

```
[Expert@MyGW:0]# cat /proc/ppk/<SecureXL Instance ID>/statistics
```

### Syntax for IPv6

```
[Expert@MyGW:0]# ls -lR /proc/ppk6/
```

```
[Expert@MyGW:0]# cat /proc/ppk6/statistics
```

```
[Expert@MyGW:0]# cat /proc/ppk6/<SecureXL Instance ID>/statistics
```

## Example for IPv4

```
[Expert@MyGW:0]# cat /proc/ppk/statistics
```

| Name                 | Value    | Name                 | Value  |

```
[Expert@MyGW:0]#
```

# /proc/ppk/stats

## Description

Contains the IRQ numbers and names of interfaces the SecureXL uses.

## Syntax for IPv4

```
[Expert@MyGW:0]# ls -lR /proc/ppk/
```

```
[Expert@MyGW:0]# cat /proc/ppk/stats
```

## Syntax for IPv6

```
[Expert@MyGW:0]# ls -lR /proc/ppk6/
```

```
[Expert@MyGW:0]# cat /proc/ppk6/stats
```

## Example for IPv4

```
[Expert@MyGW:0]# cat /proc/ppk/stats
IRQ | Interface
-----
18   eth0
16   eth1
17   eth2
18   eth3
19   eth4
[Expert@MyGW:0]#
```

# /proc/ppk/viol\_statistics

## Description

Contains SecureXL statistics for violations - packets SecureXL forwarded (F2F) to the Firewall.

 **Note** - This is the same information that the "fwaccel stats -p" command shows (see ["fwaccel stats" on page 1583](#)).

## Syntax for IPv4

```
[Expert@MyGW:0]# ls -lR /proc/ppk/
```

```
[Expert@MyGW:0]# cat /proc/ppk/viol_statistics
```

## Syntax for IPv6

```
[Expert@MyGW:0]# ls -lR /proc/ppk6/
```

```
[Expert@MyGW:0]# cat /proc/ppk6/viol_statistics
```

## Example for IPv4

```
[Expert@MyGW:0]# cat /proc/ppk/viol_statistics
```

| Violation            | Packets   | Violation            | Packets |
|----------------------|-----------|----------------------|---------|
| -----                | -----     | -----                | -----   |

| chain forwarding     | 0         | F2V conn match pkts  | 0       |
| general reason       | 0         | route changes        | 0       |

```
[Expert@MyGW:0]#
```

# SecureXL Debug

To understand how SecureXL processes the traffic, enable the SecureXL debug while the traffic passes through the Security Gateway / ClusterXL / Scalable Platform Security Group.

 **Warning** - Debug increases the load on the CPU on the Security Gateway / Cluster Members / Security Group Members. We recommend you schedule a maintenance window to debug the SecureXL.

For the complete debug procedure, see the [R82.10 Security Gateway Guide](#) > Chapter "Kernel Debug".

# fwaccel dbg

## Description

The *fwaccel dbg* command controls the SecureXL debug. See ["SecureXL Debug Procedure" on page 1702](#).

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the Gaia Portal of the applicable Security Group.
- If you do **not** use the complete debug procedure with the "fw ctl kdebug" command, and SecureXL works in User Mode (UPPAK), then Security Gateway writes the debug outputs to these files:
  - \$FWDIR/log/fw.kelg - Processing of traffic in the Firewall module
  - /var/log/usim\_x86.kelg - Processing of traffic in SecureXL
  - /var/log/messages - Processing of traffic in the ADP module (NVIDIA ConnectX 100G Cards)

## Syntax in Gaia Clish or the Expert mode on a Security Gateway / ClusterXL:

```
fwaccel dbg
  -h
  -m <Name of SecureXL Debug Module>
  all
  + <Debug Flags>
  - <Debug Flags>
  reset
  -f {"<5-Tuple Debug Filter>" | reset}
  list
  resetall
```

**Syntax in Gaia gClish on a Scalable Platform Security Group:**

```
fwaccel dbg
  -h
  -m <Name of SecureXL Debug Module>
  all
  + <Debug Flags>
  - <Debug Flags>
  reset
  -f {"<5-Tuple Debug Filter>" | reset}
  list
  resetall
```

**Syntax in the Expert mode on a Scalable Platform Security Group:**

```
g_fwaccel dbg
  -h
  -m <Name of SecureXL Debug Module>
  all
  + <Debug Flags>
  - <Debug Flags>
  reset
  -f {"<5-Tuple Debug Filter>" | reset}
  list
  resetall
```

**Parameters**

| Parameter                          | Description                                                                                                                 |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| -h                                 | Shows the applicable built-in help.                                                                                         |
| -m <Name of SecureXL Debug Module> | Specifies the name of the SecureXL debug module.<br>To see the list of available debug modules, run: <div>fwaccel dbg</div> |
| all                                | Enables all debug flags for the specified debug module.                                                                     |

| Parameter                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| - <Debug Flags>             | <p>Disables all debug flags for the specified debug module.</p> <p>Syntax:</p> <pre>- Flag1 [Flag2 Flag3 ... FlagN]</pre> <p> <b>Note</b> - You must press the space bar key after the minus (-) character.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| reset                       | Resets all debug flags for the specified debug module to their default state.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| -f "<5-Tuple Debug Filter>" | <p>Configures the debug filter to show only debug messages that contain the specified connection.</p> <p>The filter is a string of five numbers separated with commas:</p> <pre>"&lt;Source IP Address&gt;,&lt;Source Port&gt;,&lt;Destination IP Address&gt;,&lt;Destination Port&gt;,&lt;Protocol Number&gt;"</pre> <p> <b>Notes:</b></p> <ul style="list-style-type: none"> <li>■ You can configure only one debug filter at one time.</li> <li>■ You can use the asterisk "*" as a wildcard for an IP Address, Port number, or Protocol number.</li> <li>■ For more information, see <a href="#">IANA Service Name and Port Number Registry</a> and <a href="#">IANA Protocol Numbers</a>.</li> </ul> |
| -f reset                    | Resets the current debug filter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| list                        | Shows all enabled debug flags in all debug modules.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| resetall                    | Reset all debug flags for all debug modules to their default state.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Enabling SecureXL debug flags during boot

From R81.20, you can configure SecureXL debug to start during boot.

**Important** - In a Cluster, you must configure all the Cluster Members in the same way.

### Procedure

| Step | Instructions                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1    | Connect to the command line on the Security Gateway / each Cluster Member. On Scalable Platforms, you must connect to the Gaia Portal of the applicable Security Group.                                                                                                                                                                                                                                                                   |
| 2    | Log in to the Expert mode.                                                                                                                                                                                                                                                                                                                                                                                                                |
| 3    | Create the require configuration files: <ul style="list-style-type: none"> <li>To collect the debug for IPv4 traffic:               <pre>touch \$FWDIR/conf/fwaccel_dbg_flags.cfg</pre> </li> <li>To collect the debug for IPv6 traffic:               <pre>touch \$FWDIR/conf/fwaccel6_dbg_flags.cfg</pre> </li> </ul>                                                                                                                   |
| 4    | Edit the applicable configuration file: <ul style="list-style-type: none"> <li>To collect the debug for IPv4 traffic:               <pre>vi \$FWDIR/conf/fwaccel_dbg_flags.cfg</pre> </li> <li>To collect the debug for IPv6 traffic:               <pre>vi \$FWDIR/conf/fwaccel6_dbg_flags.cfg</pre> </li> </ul>                                                                                                                         |
| 5    | Configure the applicable debug modules and the debug flags (see <a href="#">R82.10 Security Gateway Guide</a> ).<br>Write each debug module and its flags on a separate line: <pre>&lt;Name of Debug Module #1&gt; &lt;Flag1&gt; &lt;Flag2&gt; &lt;Flag3&gt; ... &lt;FlagN&gt; &lt;Name of Debug Module #2&gt; &lt;Flag1&gt; &lt;Flag2&gt; &lt;Flag3&gt; ... &lt;FlagN&gt;</pre> <p>Example:</p> <pre>default conn nat pkt drop nat</pre> |
| 6    | Save the changes in the file and exit the editor.                                                                                                                                                                                                                                                                                                                                                                                         |

| Step | Instructions                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

On Scalable Platforms, you must connect to the Gaia Portal of the applicable Security Group.                                                                                                                                                                                                                                                                                                                                                                                                             |
| 11   | Log in to the Expert mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| 14   | <p>Collect the output files:</p> <ul style="list-style-type: none"> <li>\$FWDIR/log/fwk.elg</li> <li>/var/log/usim_x86.elg</li> <li>/var/log/messages</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Examples

## Example 1 - Default output

```
[Expert@MyGW:0]# fwaccel dbg
Usage: fwaccel dbg [-m <...>] [resetall | reset | list | all | +/- <flags>]
  -m <module>           - module of debugging
  -h                     - this help message
  resetall              - reset all debug flags for all modules
  reset                 - reset all debug flags for module
  all                   - set all debug flags for module
  list                  - list all debug flags for all modules
  -f reset | "<5-tuple>" - filter debug messages
  + <flags>              - set the given debug flags
  - <flags>              - unset the given debug flags
```

Debug flags can be enabled at boot by adding them to  
 \$FWDIR/conf/fwaccel\_dbg\_flags.cfg and \$FWDIR/conf/fwaccel6\_dbg\_flags.cfg.  
 The file format is one line per module.

For example, to enable "tcp\_state" and "routing" for the "pkt" module:  
 echo "pkt tcp\_state routing" >> \$FWDIR/conf/fwaccel\_dbg\_flags.cfg

List of available modules and flags:

[Expert@MyGW:0]#
```

## Example 2 - Enabling and disabling of debug flags

```
[Expert@MyGW:0]# fwaccel dbg -m default + conn
Debug flags updated.
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dbg list

[Expert@MyGW:0]# fwaccel dbg list
Module: default (400)
conn

Module: db (0)

Module: api (0)

Module: pkt (0)

Module: infras (0)

Module: tmpl (0)

Module: vpn (0)

Module: nac (0)

Module: cpaq (0)

Module: synatk (0)

Module: adp (0)

Module: dos (0)

Module: gtp (0)

Module: usdisp (0)

Module: dpdk_lib (0)

Module: dpdk_pmd (0)

Module: dpdk_other (0)

Debug filter not set.
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dbg -m default - conn
Debug flags updated.
[Expert@MyGW:0]#
```

```
[Expert@MyGW:0]# fwaccel dbg list

Module: default (0)

Module: db (0)

Module: api (0)

Module: pkt (0)

Module: infras (0)

Module: tmpl (0)

Module: vpn (0)

Module: nac (0)

Module: cpaq (0)

Module: synatk (0)

Module: adp (0)

Module: dos (0)

Module: gtp (0)

Module: usdisp (0)

Module: dpdk_lib (0)

Module: dpdk_pmd (0)

Module: dpdk_other (0)

Debug filter not set.
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dbg -m default reset
Debug flags updated.
[Expert@MyGW:0]#
```

### Example 3 - Resetting all debug flags in all debug modules

```
[Expert@MyGW:0]# fwaccel dbg resetall
Debug state was reset to default.
[Expert@MyGW:0]#
```

**Example 4 - Configuring debug filter for an SSH connection from 192.168.20.30 to 172.16.40.50**

```
[Expert@MyGW:0]# fwaccel dbg -f 192.168.20.30,*,172.16.40.50,22,6
Debug filter was set.
[Expert@MyGW:0]#
[Expert@MyGW:0]# fwaccel dbg list

... ..

Debug filter: "<*,*,*,*,*>"
[Expert@MyGW:0]#
```

# SecureXL Debug Procedure

By default, SecureXL writes the output debug information to the `/var/log/messages` file.

To collect the applicable SecureXL debug and to make its analysis easier, follow the steps below.

 **Note** - For the complete debug procedure, see the [R82.10 Security Gateway Guide](#) > Chapter "Kernel Debug".

 **Important:**

- We strongly recommend to schedule a full maintenance window to minimize the impact on your production traffic.
- We strongly recommend to connect over serial console to your Security Gateway / each Cluster Member / Scalable Platform Security Group Members. This is to prevent a possible issue when you cannot work with the CLI because of a high load on the CPU.
- In cluster, you must collect this debug from all Cluster Members in the same way.
- Debug the specific SecureXL instance only when you are sure that only that SecureXL instance processes the traffic.

## Procedure

1. **Connect to the command line on your Security Gateway / each Cluster Member / Scalable Platform Security Group**

Use an SSH or a console connection.

 **Best Practice** - Use a console connection.

**Note** - On Scalable Platforms, you must connect to the Gaia Portal of the applicable Security Group.

2. **Log in to the Expert mode**

If the default shell is Gaia Clish, run:

```
expert
```

3. **Reset all kernel debug flags in all kernel debug modules**

- On the Security Gateway / each Cluster Member, run:

```
fw ctl debug 0
```

- On the Scalable Platform Security Group, run:

```
g_fw ctl debug 0
```

#### 4. Reset all the SecureXL debug flags in all SecureXL debug modules

- On the Security Gateway / each Cluster Member:

```
fwaccel dbg resetall
```

- On the Scalable Platform Security Group:

```
g_fwaccel dbg resetall
```

#### 5. Allocate the kernel debug buffer

- On the Security Gateway / each Cluster Member, run:

```
fw ctl debug -buf 8200 [-v {"<List of VSIDs>" | all}]
```

- On the Scalable Platform Security Group, run:

```
g_fw ctl debug -buf 8200 [-v {"<List of VSIDs>" | all}]
```

 **Note** - The optional part "-v {"<List of VSIDs>" | all}" is to specify the applicable Virtual Systems on a VSX Gateway or VSX Cluster Member.

#### 6. Make sure the Security Gateway allocated the kernel debug buffer

- On the Security Gateway / each Cluster Member, run:

```
fw ctl debug | grep buffer
```

- On the Scalable Platform Security Group, run:

```
g_fw ctl debug | grep buffer
```

#### 7. Configure the applicable kernel debug modules and kernel debug flags

- On the Security Gateway / each Cluster Member, run:

```
fw ctl debug -m <Name of Kernel Debug Module> {all | +  
<Kernel Debug Flags>}
```

- On the Scalable Platform Security Group, run:

```
g_fw ctl debug -m <Name of Kernel Debug Module> {all | +  
<Kernel Debug Flags>}
```

## 8. Configure the applicable SecureXL debug modules and SecureXL debug flags

- On the Security Gateway / each Cluster Member:

```
fwaccel dbg -m <Name of SecureXL Debug Module> {all | +  
<SecureXL Debug Flags>}
```

- On the Scalable Platform Security Group:

```
g_fwaccel dbg -m <Name of SecureXL Debug Module> {all |  
+ <SecureXL Debug Flags>}
```

See "[SecureXL Debug Modules and Debug Flags](#)" on page 1708.

## 9. Examine the kernel debug configuration for kernel debug modules

- On the Security Gateway / each Cluster Member, run:

```
fw ctl debug
```

- On the Scalable Platform Security Group, run:

```
g_fw ctl debug
```

## 10. Examine the SecureXL debug configuration for SecureXL debug modules

- On the Security Gateway / each Cluster Member:

```
fwaccel dbg list
```

- On the Scalable Platform Security Group:

```
g_fwaccel dbg list
```

## 11. Remove all entries from both the Firewall Connections table and SecureXL Connections table

**Important:**

- This step makes sure that you collect the debug of the real issue that is not affected by the existing connections.
- **This command deletes all existing connections. This interrupts all connections, including the SSH.**

Run this command only if you are connected over a serial console to your Security Gateway / each Cluster Member / Scalable Platform Security Group Members.

- On the Security Gateway / each Cluster Member, run:

```
fw tab -t connections -x -y
```

- On the Scalable Platform Security Group, run:

```
g_fw tab -t connections -x -y
```

**12. Remove all entries from the Firewall Templates table**

**Note** - This command does **not** interrupt the existing connections. This step makes sure that you collect the debug of the real issue that is not affected by the existing connection templates.

- On the Security Gateway / each Cluster Member, run:

```
fw tab -t cphwd_tmpl -x -y
```

- On the Scalable Platform Security Group, run:

```
g_fw tab -t cphwd_tmpl -x -y
```

**13. Start the kernel debug****In Gateway mode:**

- On the Security Gateway / each Cluster Member, run:

```
fw ctl kdebug -T -f -o /var/log/kernel_debug.txt
```

- On the Scalable Platform Security Group, run:

```
g_fw ctl kdebug -T -f -o /var/log/kernel_debug.txt
```

**In VSX mode - for specific Virtual Systems:**

- On the VSX Gateway / each VSX Cluster Member, run:

```
fw ctl kdebug -v {"<List of VSIDs>" | all} -k -T -f -o  
/var/log/kernel_debug.txt
```

- On the Scalable Platform Security Group in VSX mode, run:

```
g_fw ctl kdebug -v {"<List of VSIDs>" | all} -k -T -f -o  
/var/log/kernel_debug.txt
```

**14. Replicate the issue, or wait for the issue to occur**

Perform the steps that cause the issue to occur, or wait for it to occur.

**15. Stop the kernel debug**

Press **CTRL+C**.

**16. Reset all kernel debug flags in all kernel debug modules**

- On the Security Gateway / each Cluster Member, run:

```
fw ctl debug 0
```

- On the Scalable Platform Security Group, run:

```
g_fw ctl debug 0
```

**17. Reset all the SecureXL debug flags in all SecureXL debug modules**

- On the Security Gateway / each Cluster Member:

```
fwaccel dbg resetall
```

- On the Scalable Platform Security Group:

```
g_fwaccel dbg resetall
```

**18. Examine the kernel debug configuration to make sure it returned to the default**

- On the Security Gateway / each Cluster Member, run:

```
fw ctl debug
```

- On the Scalable Platform Security Group, run:

```
g_fw ctl debug
```

## 19. Examine the SecureXL debug configuration to make sure it returned to the default

- On the Security Gateway / each Cluster Member:

```
fwaccel dbg list
```

- On the Scalable Platform Security Group:

```
g_fwaccel dbg list
```

## 20. Analyze the debug output files

Transfer these files from the Security Gateway / each Cluster Member / each Security Group Member to your computer:

```
/var/log/kernel_debug.txt
```

```
/var/log/messages*
```

```
$FWDIR/log/fwkw.elg*
```

```
/var/log/usim_x86.elg*
```

- ★ **Best Practice** - Compress these files with the "`tar -zxvf`" command and transfer the archive from the Security Gateway / each Cluster Member / each Security Group Member to your computer. If you transfer to an FTP server, do so in the binary mode.

## SecureXL Debug Modules and Debug Flags

To see the available SecureXL debug modules and their debug flags, run the ["fwaccel dbg" on page 1689](#) command.

### Module "default"

| Flag      | Description                                                            |
|-----------|------------------------------------------------------------------------|
| acct      | Connection accounting information                                      |
| ant       | Anticipated connections                                                |
| conf      | Configuration of the SecureXL (for example, interfaces)                |
| conn      | Processing of connections                                              |
| conn_app  | Processing of connections                                              |
| corr      | Correction layer                                                       |
| cpdrv     | <i>Currently not in use</i>                                            |
| del       | Deletion of connections                                                |
| drv       | Driver information                                                     |
| htab      | Hash table                                                             |
| infra_ids | Allocating IDs for a given range in Identity Awareness                 |
| init      | Initialization                                                         |
| ioctl     | Changes in the configuration, which were initiated from the user space |
| iter      | Connection table iterator                                              |
| kdrv      | Driver information                                                     |
| lock      | Lock initializing and finalizing                                       |
| nat       | Processing of NAT connections                                          |
| offload   | Offloading of connections from the Firewall to the SecureXL            |
| queue     | Connections queue                                                      |
| relations | Related connections (such as FTP data connections)                     |
| rngs      | Handling of SecureXL ranges                                            |

| Flag                    | Description                                                                                         |
|-------------------------|-----------------------------------------------------------------------------------------------------|
| <code>rngs_print</code> | Printing of SecureXL ranges                                                                         |
| <code>routing</code>    | Handling of SecureXL routing                                                                        |
| <code>stat</code>       | Handling of SecureXL statistics                                                                     |
| <code>svm</code>        | Registering templates or connections for System Counters in Security Gateway object in SmartConsole |
| <code>tag</code>        | Tags that were added to the packets by the SecureXL before forwarding them to the Firewall          |
| <code>tcp_sv</code>     | Verification of sequence in TCP packets                                                             |
| <code>update</code>     | Updates of connections                                                                              |
| <code>util</code>       | Utilization                                                                                         |

**Module "pkt" (Packet)**

| Flag                 | Description                                                                                             |
|----------------------|---------------------------------------------------------------------------------------------------------|
| <code>acct</code>    | Connection accounting information                                                                       |
| <code>bhm</code>     | BHM Statistics for each CPU                                                                             |
| <code>caf</code>     | Mirror and Decrypt feature - Mirror only of all traffic                                                 |
| <code>corr</code>    | Correction layer                                                                                        |
| <code>cpls</code>    | ClusterXL Load Sharing                                                                                  |
| <code>deliver</code> | Packet delivery                                                                                         |
| <code>drop</code>    | Packets dropped by SecureXL                                                                             |
| <code>f2f</code>     | Reason for forwarding a packet to the Firewall                                                          |
| <code>frag</code>    | Processing of fragments                                                                                 |
| <code>geneve</code>  | Processing of Generic Network Virtualization Encapsulation (Geneve) packets in GRE and VxLAN interfaces |
| <code>nat</code>     | Processing of NAT connections                                                                           |
| <code>notif</code>   | Notifications sent to the Firewall                                                                      |

| Flag          | Description                                                                                                                                  |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| pkt           | Processing of packets                                                                                                                        |
| pxl           | PXL (PacketXL) handling - API between the SecureXL and PSL (Packet Streaming Layer), which is a TCP Streaming engine that parses TCP streams |
| qos           | QoS acceleration                                                                                                                             |
| routing       | Handling of SecureXL routing                                                                                                                 |
| sctp          | Handling of Stream Control Transmission Protocol (SCTP) packets                                                                              |
| spoof         | Handling of SecureXL Anti-Spoofing                                                                                                           |
| sv            | Validation of sequence in TCP packets                                                                                                        |
| tcp_state     | Validation of TCP state in TCP packets                                                                                                       |
| tcp_state_pkt | Validation of TCP packets                                                                                                                    |
| user          | Details of a packet                                                                                                                          |
| vlan          | Handling of VLAN tags                                                                                                                        |
| wrp           | Handling of WRP interfaces in VSX                                                                                                            |

#### Module "db" (Database)

| Flag | Description                                                                                                                                                         |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ant  | Anticipated connections                                                                                                                                             |
| del  | Deleting of data from the SecureXL database                                                                                                                         |
| get  | Retrieving of data from the SecureXL database                                                                                                                       |
| init | Initializing and finalizing of SecureXL database                                                                                                                    |
| nmr  | "No Match Ranges" templates, which allow SecureXL Accept Templates for rules that contain Dynamic objects or Domain objects (or for rules located below such rules) |

| Flag    | Description                                                                                                                                  |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------|
| nmt     | "No Match Time" templates, which allow SecureXL Accept Templates for rules that contain Time objects (or for rules located below such rules) |
| profile | Operations on profile table                                                                                                                  |
| save    | Saving of data to the SecureXL database                                                                                                      |
| tmo     | Handling of timeouts for SecureXL database entries                                                                                           |
| tmpl    | Handling of SecureXL templates database                                                                                                      |
| warning | General failures to process a packet                                                                                                         |

### Module "api" (Application Programmable Interface)

| Flag         | Description                                                     |
|--------------|-----------------------------------------------------------------|
| acct         | Connection accounting information                               |
| add          | Adding of connections                                           |
| add_sa       | Offloading of VPN SA to SecureXL                                |
| conf         | Configuration of the SecureXL (for example, interfaces)         |
| del          | Deletion of connections                                         |
| del_all_sas  | Deletion of all VPN SAs from SecureXL                           |
| del_all_tmpl | Deletion of the SecureXL Templates                              |
| del_sa       | Deletion of VPN SA from SecureXL                                |
| get_features | Getting features buffer (in SecureXL initialization)            |
| get_stat     | Retrieving of SecureXL statistics                               |
| get_state    | Getting the connection state from SecureXL                      |
| get_tab      | Some extra printouts when processing SecureXL tables            |
| gtp          | Processing of GPRS Tunnelling Protocol (GTP) tunnel connections |

| Flag         | Description                                                                                                                                  |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| infra        | SecureXL infrastructure                                                                                                                      |
| init         | Enabling and disabling of SecureXL                                                                                                           |
| long_ver     | Prints additional verbose information about connections                                                                                      |
| misc         | Prints additional information about SecureXL internals                                                                                       |
| notif        | Notifications sent to the Firewall                                                                                                           |
| pxl          | PXL (PacketXL) handling - API between the SecureXL and PSL (Packet Streaming Layer), which is a TCP Streaming engine that parses TCP streams |
| qos          | QoS acceleration                                                                                                                             |
| reset_stat   | Prints statistics IDs that are reset                                                                                                         |
| stat         | Handling of SecureXL statistics                                                                                                              |
| sv           | Validation of sequence in TCP packets                                                                                                        |
| tag          | Tags that were added to the packets by the SecureXL before forwarding them to the Firewall                                                   |
| tmpl         | Handling of SecureXL Templates                                                                                                               |
| tmpl_info    | Information about SecureXL Templates                                                                                                         |
| upd_conf     | Update of SecureXL in ClusterXL Load Sharing                                                                                                 |
| upd_if_inf   | Prints some text that shows if SecureXL updated information about interfaces                                                                 |
| upd_link_sel | Updates of VPN Link Selection                                                                                                                |
| update       | Updates of connections                                                                                                                       |
| vpn          | Processing of VPN connection                                                                                                                 |

**Module "adp" (NVIDIA ConnectX 100G Cards)**

| Flag       | Description                                                                |
|------------|----------------------------------------------------------------------------|
| ac_print   | Prints additional information                                              |
| bond       | Information about Bond interfaces                                          |
| bpl        | Information about packet processing in the backplane                       |
| bplinf     | Information about packet processing in the backplane                       |
| cpfifo     | <i>Currently is not used</i>                                               |
| drop       | Information about packet drops in the backplane                            |
| eth        | Information about ports from the NVIDIA ConnectX 100G Card's point of view |
| filter     | Information about packet processing in the network interface               |
| heth       | Information about ports from the Host Security Appliance's point of view   |
| hw_expn    | Information about packet processing in the NVIDIA ConnectX 100G Card       |
| hw_offload | Offloading of connections from the Host Security Appliance to the SecureXL |
| if         | Information about interfaces                                               |
| inf        | Information about slots and ports                                          |
| ipsctl     | Information about slots in the Host Security Appliance                     |
| mbeinf     | Information about packet processing in the backplane                       |
| mbs        | Information about packet processing in the backplane                       |
| mcast      | Handling of multicast traffic                                              |
| nh         | Handling of next hop routing                                               |
| packet     | Information about packet processing in the NVIDIA ConnectX 100G Card       |
| qcomm      | Information about communication queues                                     |
| qconf      | Information about packets in the communication queues                      |
| rt         | Handling of general routing                                                |

| Flag    | Description                                                                   |
|---------|-------------------------------------------------------------------------------|
| rte_api | Detailed information about packet processing in the NVIDIA ConnectX 100G Card |
| wrp     | Handling of WRP interfaces in VSX                                             |
| xmode   | Events in the known neighbors database                                        |

#### Module "infras" (Identity Awareness - Identities Infrastructure)

| Flag    | Description                    |
|---------|--------------------------------|
| pm      | Pattern Matcher                |
| reorder | Reordering of packets in queue |

#### Module "nac" (Identity Awareness - Network Access Control)

| Flag      | Description                                                                                                              |
|-----------|--------------------------------------------------------------------------------------------------------------------------|
| db        | Updating, adding, deleting of identities                                                                                 |
| db_get    | Updating, fetching, searching of identities                                                                              |
| idnt      | Identity Tags                                                                                                            |
| ioctl     | Changes in the configuration, which were initiated from the user space                                                   |
| nac       | Network Access Control                                                                                                   |
| offload   | Offloading of connections from the Firewall to the SecureXL                                                              |
| pkt       | Forwarding of connections to Firewall (when identity is not found or revoked, or NAC packet tagging verification failed) |
| pkt_ex    | NAC packet-tagging verification                                                                                          |
| signature | Signing of packets                                                                                                       |

#### Module "vpn" (VPN)

| Flag    | Description        |
|---------|--------------------|
| linksel | VPN Link Selection |

| Flag    | Description                                                                    |
|---------|--------------------------------------------------------------------------------|
| ls      | Forwarding of packets between Cluster Members in a ClusterXL Load Sharing mode |
| routing | VPN Encryption routing information                                             |
| vpn     | Processing of VPN connections                                                  |
| vpnpkt  | Processing of VPN packets                                                      |

#### Module "cpaq" (Internal Asynchronous Queue)

| Flag            | Description                                            |
|-----------------|--------------------------------------------------------|
| broadcast       | Processing of broadcast packets                        |
| cbuf            | Information about queue buffers                        |
| client          | Information about queue clients                        |
| error           | General errors                                         |
| exp             | Information about expiration of queue items            |
| init            | Initializing of queue                                  |
| opreg           | <i>Currently not in use</i>                            |
| server          | Information about queue servers                        |
| transport       | Information about sending messages in queue            |
| transport_utils | Additional information about sending messages in queue |

#### Module "dos" (Denial of Service Defender)

| Flag         | Description                                                                                                                                                                                                                 |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cache        | <i>Currently not in use</i>                                                                                                                                                                                                 |
| detailed-cfg | Detailed information about DoS Rate Limiting configuration.<br><b>Important</b> - This debug flag is not suitable for large traffic volumes because it prints a large number of messages. This causes high load on the CPU. |

| Flag         | Description                                                                                                                                                                                                               |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| detailed-pkt | Detailed information about DoS Rate Limiting packet flow.<br><b>Important</b> - This debug flag is not suitable for large traffic volumes because it prints a large number of messages. This causes high load on the CPU. |
| drop         | Dropped packets                                                                                                                                                                                                           |
| fwl-cfg      | Information about DoS Rate Limiting configuration in the Firewall kernel module                                                                                                                                           |
| fwl-pkt      | Information about DoS Rate Limiting packet flow in the Firewall kernel module                                                                                                                                             |
| sim-cfg      | Information about DoS Rate Limiting configuration in the SecureXL kernel module                                                                                                                                           |
| sim-pkt      | Information about DoS Rate Limiting packet flow in the SecureXL kernel module                                                                                                                                             |

#### Module "synatk" (Accelerated SYN Defender)

| Flag  | Description                                                                    |
|-------|--------------------------------------------------------------------------------|
| conf  | Receiving and updating of Accelerated SYN Defender module's configuration      |
| conn  | Handling of TCP connections                                                    |
| init  | Initializing of the Accelerated SYN Defender module                            |
| log   | Prints time of the last sent monitor log and interval between the monitor logs |
| msg   | Information about internal messages in the Accelerated SYN Defender module     |
| pkt   | Handling of TCP packets                                                        |
| proxy | <i>Currently not in use</i>                                                    |
| state | Information about states of the Accelerated SYN Defender module                |

**Module "tmpl" (Drop Templates)**

| Flag        | Description                        |
|-------------|------------------------------------|
| dtmpl_get   | Getting of Drop Templates          |
| dtmpl_notif | Notifications about Drop Templates |
| tmpl        | Information about Drop Templates   |

**Module "gtp" (GPRS Tunnelling Protocol (GTP))**

| Flag    | Description                                     |
|---------|-------------------------------------------------|
| api     | Information about GTP tunnels in kernel tables  |
| drop    | Drops of GTP packets                            |
| general | General information about APN and kernel tables |
| notif   | Information about notification messages         |
| pkt     | Processing of GTP packets                       |
| policy  | APN information                                 |
| tables  | Operations in kernel tables                     |

**Module "usdisp" (User Space Dispatcher)**

| Flag     | Description                 |
|----------|-----------------------------|
| api      | <i>Currently not in use</i> |
| cachetab | <i>Currently not in use</i> |
| clb      | <i>Currently not in use</i> |
| conn     | Processing of connections   |
| counter  | <i>Currently not in use</i> |
| dumbo    | <i>Currently not in use</i> |
| error    | General errors              |
| event    | <i>Currently not in use</i> |

| Flag       | Description                                                                    |
|------------|--------------------------------------------------------------------------------|
| fwstats    | <i>Currently not in use</i>                                                    |
| ioctl      | IOCTL control messages (communication between kernel and user space processes) |
| lock       | <i>Currently not in use</i>                                                    |
| msg        | <i>Currently not in use</i>                                                    |
| packet     | Processing of packets                                                          |
| packet_err | Processing of packets                                                          |
| prio       | <i>Currently not in use</i>                                                    |
| queue      | <i>Currently not in use</i>                                                    |
| quota      | <i>Currently not in use</i>                                                    |
| route      | <i>Currently not in use</i>                                                    |
| state      | <i>Currently not in use</i>                                                    |
| temp_conns | Shows the selected CoreXL Firewall instance                                    |
| uid        | <i>Currently not in use</i>                                                    |
| vpn        | <i>Currently not in use</i>                                                    |

# CoreXL Commands

For more information about CoreXL, see the [R82.10 Performance Tuning Administration Guide](#) - Chapter *CoreXL*.

# cp\_conf corexl

## Description

Enables or disables CoreXL.

For more information, see the [R82.10 Performance Tuning Administration Guide](#).

### Important:

- This command is for Check Point use only.  
To configure CoreXL, use the **Check Point CoreXL** option in the "*cpconfig*" on [page 1002](#) menu.
- After all changes in CoreXL configuration on the Security Gateway / Cluster Member / Security Group, you must reboot it.
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the Gaia Portal of the applicable Security Group.

## Syntax on a Security Gateway / Cluster Member in Gaia Clish or the Expert mode

- To enable CoreXL with 'n' IPv4 Firewall instances and optionally 'k' IPv6 Firewall instances:

```
cp_conf corexl [-v] enable [n] [-6 k]
```

- To disable CoreXL:

```
cp_conf corexl [-v] disable
```

## Syntax on a Scalable Platform Security Group in Gaia gClish

- To enable CoreXL with 'n' IPv4 Firewall instances and optionally 'k' IPv6 Firewall instances:

```
cp_conf corexl [-v] enable [n] [-6 k]
```

- To disable CoreXL:

```
cp_conf corexl [-v] disable
```

## Syntax on a Scalable Platform Security Group in the Expert mode

- To enable CoreXL with 'n' IPv4 Firewall instances and optionally 'k' IPv6 Firewall instances:

```
g_all cp_conf corexl [-v] enable [n] [-6 k]
```

- To disable CoreXL:

```
g_all cp_conf corexl [-v] disable
```

The related command is: ["fwboot corexl" on page 1304](#).

## Parameters

| Parameter | Description                                           |
|-----------|-------------------------------------------------------|
| -v        | Leaves the high memory (vmalloc) unchanged.           |
| n         | Denotes the number of IPv4 CoreXL Firewall instances. |
| k         | Denotes the number of IPv6 CoreXL Firewall instances. |

## Example

Currently, the Security Gateway runs two IPv4 CoreXL Firewall instances (`KERN_INSTANCE_NUM = 2`).

We change the number of IPv4 CoreXL Firewall instances to three.

```
[Expert@MyGW:0]# fw ctl multik stat
ID | Active | CPU | Connections | Peak
-----
0 | Yes | 2 | 7 | 28
1 | Yes | 1 | 0 | 11
[Expert@MyGW:0]#
[Expert@MyGW:0]# cat /etc/fw.boot/boot.conf
CTL_IPFORWARDING 1
DEFAULT_FILTER_PATH 0
KERN_INSTANCE_NUM 2
COREXL_INSTALLED 1
KERN6_INSTANCE_NUM 2
IPV6_INSTALLED 0
CORE_OVERRIDE 4
[Expert@MyGW:0]#
[Expert@MyGW:0]# cp_conf corexl -v enable 3
[Expert@MyGW:0]#
[Expert@MyGW:0]# cat /etc/fw.boot/boot.conf
CTL_IPFORWARDING 1
DEFAULT_FILTER_PATH 0
KERN_INSTANCE_NUM 3
COREXL_INSTALLED 1
KERN6_INSTANCE_NUM 2
IPV6_INSTALLED 0
CORE_OVERRIDE 4
[Expert@MyGW:0]#
[Expert@MyGW:0]# reboot
.. .. .
[Expert@MyGW:0]# fw ctl multik stat
ID | Active | CPU | Connections | Peak
-----
0 | Yes | 3 | 7 | 28
1 | Yes | 2 | 0 | 11
2 | Yes | 1 | 4 | 10
[Expert@MyGW:0]#
```

# dynamic\_balancing

## Description

On Check Point Appliances, R80.40 added the ability to change the number of CoreXL Firewall and SND instances without reboot (Dynamic Balancing).

### Important:

- By default, this feature is *enabled*.
- We do **not** recommend manual configuration of CoreXL Firewall and SND instances, because such configuration *disables* the CoreXL Dynamic Balancing.  
To enable the CoreXL Dynamic Balancing again, you must disable it and enable it.
- For CoreXL Dynamic Balancing requirements, see [sk164155](#).

The "dynamic\_balancing" command in the Expert mode (and the command "set dynamic-balancing state" in Gaia Clish) controls the Dynamic Balancing of CoreXL Firewall and SND instances on the local Security Gateway, or Cluster Member.

For more information, see [R82.10 Performance Tuning Administration Guide](#) - Chapter CoreXL.

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.

Syntax

| Shell          | Security Gateway (each Cluster Member)                                                                                                                                | Security Group on a Scalable Platform                                                                                                                                 |

Example

```
[Expert@MyGW:0]# dynamic_balancing -p
Dynamic Balancing is currently On
[Expert@MyGW:0]#
```

# fw ctl multik

## Description

The "fw ctl multik" and "fw6 ctl multik" commands control CoreXL for IPv4 and IPv6, respectively.

## Syntax for IPv4

```
fw ctl multik
  add_bypass_port <options>
  del_bypass_port <options>
  dynamic_dispatching <options>
  gconn <options>
  get_instance <options>
  heavy_conn_analyzer
  print_heavy_conn
  prioq <options>
  queues
  show_bypass_ports
  snd_dist <options>
  stat
  start
  stop
  utilize
```

## Syntax for IPv6

```
fw6 ctl multik
  add_bypass_port <options>
  del_bypass_port <options>
  dynamic_dispatching <options>
  gconn <options>
  get_instance <options>
  heavy_conn_analyzer
  print_heavy_conn
  prioq <options>
  queues
  show_bypass_ports
  snd_dist <options>
  stat
  start
  stop
  utilize
```

## Parameters

| Parameter                        | Description                                                                                                                                                   |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| add_bypass_port<br><options>     | Adds the specified TCP and UDP ports to the CoreXL Dynamic Dispatcher bypass list.<br>See <a href="#">"fw ctl multik add_bypass_port" on page 1730</a> .      |
| del_bypass_port<br><options>     | Removes the specified TCP and UDP ports from the CoreXL Dynamic Dispatcher bypass list.<br>See <a href="#">"fw ctl multik del_bypass_port" on page 1732</a> . |
| dynamic_dispatching<br><options> | Shows and controls CoreXL Dynamic Dispatcher (see <a href="#">sk105261</a> ).<br>See <a href="#">"fw ctl multik dynamic_dispatching" on page 1734</a> .       |
| gconn <options>                  | Shows statistics about CoreXL Global Connections.<br>See <a href="#">"fw ctl multik gconn" on page 1735</a> .                                                 |
| get_instance<br><options>        | Shows CoreXL Firewall instance that processes the specified IPv4 connection.<br>See <a href="#">"fw ctl multik get_instance" on page 1740</a> .               |

| Parameter                               | Description                                                                                                                                                                                     |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| heavy_conn_analyzer<br>print_heavy_conn | Shows the table with Heavy Connections (that consume the most CPU resources) in the CoreXL Dynamic Dispatcher.<br>See <a href="#">"fw ctl multik print_heavy_conn" on page 1742</a> .           |
| prioq <options>                         | Configures the CoreXL Firewall Priority Queues (see <a href="#">sk105762</a> ).<br>See <a href="#">"fw ctl multik prioq" on page 1744</a> .                                                     |
| queues                                  | Shows the CoreXL Queues and their utilization.<br>This command is supported only when the SecureXL works in the User Mode (UPPAK).<br>See <a href="#">"fw ctl multik queues" on page 1745</a> . |
| show_bypass_ports                       | Shows the TCP and UDP ports configured in the bypass port list of the CoreXL Dynamic Dispatcher.<br>See <a href="#">"fw ctl multik show_bypass_ports" on page 1746</a> .                        |
| snd_dist<br><options>                   | Shows advanced information about distribution of connections by CoreXL SND instances.<br>See <a href="#">"fw ctl multik snd_dist" on page 1747</a> .                                            |
| stat                                    | Shows the CoreXL status.<br>See <a href="#">"fw ctl multik stat" on page 1750</a> .                                                                                                             |
| start                                   | Starts all CoreXL Firewall instances on-the-fly.<br>See <a href="#">"fw ctl multik start" on page 1752</a> .                                                                                    |
| stop                                    | Stops all CoreXL Firewall instances temporarily.<br>See <a href="#">"fw ctl multik stop" on page 1753</a> .                                                                                     |
| utilize                                 | Shows the CoreXL queue utilization for each CoreXL Firewall instance.<br>See <a href="#">"fw ctl multik utilize" on page 1754</a> .                                                             |

# fw ctl multik add\_bypass\_port

## Description

Adds the specified TCP and UDP ports to the bypass port list of the CoreXL Dynamic Dispatcher.

For more information about the CoreXL Dynamic Dispatcher, see [sk105261](#).

 **Important** - This command saves the configuration in the `$FWDIR/conf/dispatcher_bypass.conf` file. You must **not** edit this file manually.

## Syntax

```
fw ctl multik add_bypass_port <Port Number 1>,<Port Number 2>,...,<Port Number N>
```

## Parameters

| Parameter                        | Description                                                                                                                                                                                            |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;Port Number&gt;</code> | Specifies the numbers of TCP and UDP ports to add to the list.<br> <b>Important</b> - You can add 10 ports maximum. |

## Example

```
[Expert@MyGW:0]# fw ctl multik show_bypass_ports
dynamic dispatcher bypass port list:
[Expert@MyGW:0]#
[Expert@MyGW:0]# cat $FWDIR/conf/dispatcher_bypass.conf
dynamic_dispatcher_bypass_ports_number = 0
[Expert@MyGW:0]#
[Expert@MyGW:0]# fw ctl multik add_bypass_port 8888
[Expert@MyGW:0]#
[Expert@MyGW:0]# fw ctl multik show_bypass_ports
dynamic dispatcher bypass port list:
(8888)
[Expert@MyGW:0]
[Expert@MyGW:0]# cat $FWDIR/conf/dispatcher_bypass.conf
dynamic_dispatcher_bypass_ports_number = 1
dynamic_dispatcher_bypass_port_table=8888
[Expert@MyGW:0]
[Expert@MyGW:0]# fw ctl multik add_bypass_port 9999
[Expert@MyGW:0]#
[Expert@MyGW:0]# fw ctl multik show_bypass_ports
dynamic dispatcher bypass port list:
(8888,9999)
[Expert@MyGW:0]
[Expert@MyGW:0]# cat $FWDIR/conf/dispatcher_bypass.conf
dynamic_dispatcher_bypass_ports_number = 2
dynamic_dispatcher_bypass_port_table=8888,9999
[Expert@MyGW:0]
```

# fw ctl multik del\_bypass\_port

## Description

Removes the specified TCP and UDP ports from the bypass port list of the CoreXL Dynamic Dispatcher.

For more information about the CoreXL Dynamic Dispatcher, see [sk105261](#).

**Important** - This command saves the configuration in the `$FWDIR/conf/dispatcher_bypass.conf` file. You must **not** edit this file manually.

## Syntax

```
fw ctl multik del_bypass_port <Port Number 1>,<Port Number 2>,...,<Port Number N>
```

## Parameters

| Parameter                  | Description                                                         |
|----------------------------|---------------------------------------------------------------------|
| <i>&lt;Port Number&gt;</i> | Specifies the numbers of TCP and UDP ports to remove from the list. |

## Example

```
[Expert@MyGW:0]# fw ctl multik show_bypass_ports
dynamic dispatcher bypass port list:
[Expert@MyGW:0]#

```

# fw ctl multik dynamic\_dispatching

## Description

Shows and controls the CoreXL Dynamic Dispatcher that dynamically assigns new connections to a CoreXL Firewall instances based on the utilization of CPU cores.

For more information, see [sk105261](#).

## Syntax for IPv4

```
fw ctl multik dynamic_dispatching
  get_mode
  off
  on
```

## Syntax for IPv6

```
fw6 ctl multik dynamic_dispatching
  get_mode
  off
  on
```

## Parameters

| Parameter | Description                                               |
|-----------|-----------------------------------------------------------|
| get_mode  | Shows the current state of the CoreXL Dynamic Dispatcher. |
| off       | Disables the CoreXL Dynamic Dispatcher.                   |
| on        | Enables the CoreXL Dynamic Dispatcher.                    |

## Example

```
[Expert@MyGW:0]# fw ctl multik dynamic_dispatching get_mode
Current mode is Off
[Expert@MyGW:0]#
[Expert@MyGW:0]# fw ctl multik dynamic_dispatching on
New mode is: On
Please reboot the system
[Expert@MyGW:0]#
```

# fw ctl multik gconn

## Description

Shows statistics about CoreXL Global Connections that Security Gateway stores in the kernel table `fw_multik_ld_gconn_table`.

The CoreXL Global Connections table contains information about which CoreXL Firewall instance owns which connections.

 **Notes:**

- This command does not support VSX.
- This command does not support IPv6.

## Syntax

```
fw [-d] ctl multik gconn
    -h
    -p
    -sec
    -seg <Number>
```

## Parameters

| Parameter | Description                                                                                                                                                                                                                                                                                                                                |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d        | Runs the command in debug mode.<br>Use only if you troubleshoot the command itself.<br> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session. |
| none      | Shows the interactive menu for the CoreXL Firewall Priority Queues.                                                                                                                                                                                                                                                                        |
| -h        | Shows the built-in help.                                                                                                                                                                                                                                                                                                                   |

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -p               | Shows the additional information about each CoreXL Firewall instance, including the information about Firewall Priority Queues: <ul style="list-style-type: none"> <li>▪ I/O (In or Out)</li> <li>▪ Inst. ID (CoreXL Firewall instance ID)</li> <li>▪ Flags</li> <li>▪ Seq (Sequence)</li> <li>▪ Hold_ref (Hold reference)</li> <li>▪ Prio (Firewall Priority Queues mode)</li> <li>▪ last_enq_jiff (Jiffies since last enqueue)</li> <li>▪ queue_indx (Queue index number)</li> <li>▪ conn_tokens (Connection Tokens)</li> </ul> |
| -s               | Shows the total number of global connections.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| -sec             | Shows the additional information about each CoreXL Firewall instance: <ul style="list-style-type: none"> <li>▪ I/O (In or Out)</li> <li>▪ Inst. ID (CoreXL Firewall instance ID)</li> <li>▪ Flags</li> <li>▪ Seq (Sequence)</li> <li>▪ Hold_ref (Hold reference)</li> </ul>                                                                                                                                                                                                                                                       |
| -seg<br><Number> | Shows the default information about the specified Global Connections Segment.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

=====
FP - from pool.      T - temporary connection.      PP - pending permanent.      In - inbound.      Out
- outbound.
[Expert@MyGW:0]#
```

# fw ctl multik get\_instance

## Description

Shows CoreXL Firewall instance that processes the specified IPv4 connection.

 **Important** - This command works only if the CoreXL Dynamic Dispatcher is disabled (see [sk105261](#)).

## Syntax

- To show the CoreXL Firewall instance that processes the specified IPv4 connection:

```
fw ctl multik get_instance sip=<Source IPv4 Address>  
dip=<Destination IPv4 Address> proto=<Protocol Number>
```

- To show the CoreXL Firewall instance that processes the specified range of IPv4 connections:

```
fw ctl multik get_instance sip=<Source IPv4 Address Start> -  
<Source IPv4 Address End> dip=<Destination IPv4 Address Start>  
- <Destination IPv4 Address End> proto=<Protocol Number>
```

## Parameters

| Parameter                                           | Description                                                                                                                                                     |
|-----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;Source IPv4 Address&gt;</code>            | Source IPv4 address of the specified connection                                                                                                                 |
| <code>&lt;Source IPv4 Address Start&gt;</code>      | First source IPv4 address of the specified range of IPv4 addresses                                                                                              |
| <code>&lt;Source IPv4 Address End&gt;</code>        | Last source IPv4 address of the specified range of IPv4 addresses                                                                                               |
| <code>&lt;Destination IPv4 Address&gt;</code>       | Destination IPv4 address of the specified connection                                                                                                            |
| <code>&lt;Destination IPv4 Address Start&gt;</code> | First destination IPv4 address of the specified range of IPv4 addresses                                                                                         |
| <code>&lt;Destination IPv4 Address End&gt;</code>   | Last destination IPv4 address of the specified range of IPv4 addresses                                                                                          |
| <code>&lt;Protocol Number&gt;</code>                | See <a href="#">IANA Protocol Numbers</a> .<br>For example: <ul style="list-style-type: none"> <li>▪ 1 = ICMP</li> <li>▪ 6 = TCP</li> <li>▪ 17 = UDP</li> </ul> |

## Example for a specified IPv4 connection

```
[Expert@MyGW:0]# fw ctl multik get_instance sip=192.168.2.3 dip=172.30.241.66 proto=6
protocol: 6
192.168.2.3 -> 172.30.241.66 => 3
[Expert@MyGW:0]#
```

## Example for a specified range of IPv4 connections

```
[Expert@MyGW:0]# fw ctl multik get_instance sip=192.168.2.3-192.168.2.8 dip=172.30.241.66
proto=6
protocol: 6
192.168.2.3 -> 172.30.241.66 => 3
192.168.2.4 -> 172.30.241.66 => 0
192.168.2.5 -> 172.30.241.66 => 3
192.168.2.6 -> 172.30.241.66 => 5
192.168.2.7 -> 172.30.241.66 => 4
192.168.2.8 -> 172.30.241.66 => 5
[Expert@MyGW:0]#
```

# fw ctl multik print\_heavy\_conn

## Description

These commands show the table with Heavy Connections (that consume the most CPU resources) in the CoreXL Dynamic Dispatcher.

For more information about the CoreXL Dynamic Dispatcher, see [sk105261](#).

CoreXL suspects that a connection is "heavy" if it meets these conditions:

- Security Gateway detected the suspected connection during the last 24 hours
- The suspected connection lasts more than 10 seconds
- CoreXL Firewall instance that processes this connection causes a CPU load of over 60%
- The suspected connection utilizes more than 50% of the total work the applicable CoreXL Firewall instance does

The output table shows this information about the Heavy Connections:

- Source IP address
- Source Port
- Destination IP address
- Destination Port
- Protocol Number
- CoreXL Firewall instance ID that processes this connection
- CoreXL Firewall instance load on the CPU
- Connection's relative load on the CoreXL Firewall instance

## Notes:

- These commands shows the suspected heavy connections even if they are already closed.
- In the "[cpview](#)" on [page 1837](#) utility, go to **CPU > Top-Connections > InstancesX-Y > InstanceZ**. Refer to the **Top Connections** section.

## Syntax

```
fw [-d] ctl multik print_heavy_conn
```

```
fw [-d] ctl multik heavy_conn_analyzer
```

## Parameters

| Parameter | Description                                                                                                                                                                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d        | <p>Runs the command in debug mode.<br/>Use only if you troubleshoot the command itself.</p> <p>★ <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p> |

## Example

```
[Expert@MyGW:0]# fw ctl multik print_heavy_conn
Source: 192.168.20.31; SPort: 51006; Dest: 172.30.40.55; DPort: 80; IPP: 6; Instance 1; Instance
Load 61%; Connection instance load 100%
Source: 192.168.20.31; SPort: 50994; Dest: 172.30.40.55; DPort: 80; IPP: 6; Instance 1; Instance
Load 61%; Connection instance load 100%
Source: 192.168.20.31; SPort: 50992; Dest: 172.30.40.55; DPort: 80; IPP: 6; Instance 1; Instance
Load 61%; Connection instance load 100%
[Expert@MyGW:0]#
```

# fw ctl multik prioq

## Description

Configures the CoreXL Firewall Priority Queues. For more information, see [sk105762](#).

 **Important** - This command saves the configuration in the `$FWDIR/conf/prioq_mode.conf` file. You must **not** edit this file manually.

## Syntax for IPv4

```
fw ctl multik prioq [{0 | 1 | 2}]
```

## Syntax for IPv6

```
fw6 ctl multik prioq [{0 | 1 | 2}]
```

## Parameters

| Parameter     | Description                                                                          |
|---------------|--------------------------------------------------------------------------------------|
| No Parameters | Shows the interactive menu for configuration of the CoreXL Firewall Priority Queues. |
| 0             | Disables the CoreXL Firewall Priority Queues.                                        |
| 1             | Enables the CoreXL Firewall Priority Queues in the Evaluator-only mode.              |
| 2             | Enables the CoreXL Firewall Priority Queues.                                         |

## Example

```
[Expert@MyGW:0]# fw ctl multik prioq
Current mode is Off

Available modes:
0.      Off
1.      Evaluator-only
2.      On

Choose the desired mode number: (or 3 to Quit)
[Expert@MyGW:0]#
```

# fw ctl multik queues

## Description

Shows the CoreXL Queues and their utilization.

This command is supported only when the SecureXL works in the User Mode (UPPAK).

## Syntax for IPv4

```
fw [-d] ctl multik queues
```

## Syntax for IPv6

```
fw6 [-d] ctl multik queues
```

## Parameters

| Parameter | Description                                                                                                                                                                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d        | <p>Runs the command in debug mode.<br/>Use only if you troubleshoot the command itself.</p> <p>★ <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p> |

# fw ctl multik show\_bypass\_ports

## Description

Shows the TCP and UDP ports configured in the bypass port list of the CoreXL Dynamic Dispatcher with the *"fw ctl multik add\_bypass\_port" on page 1730* command.

For more information about the CoreXL Dynamic Dispatcher, see [sk105261](#).

**Important** - This command reads the configuration from the `$FWDIR/conf/dispatcher_bypass.conf` file. You must **not** edit this file manually.

## Syntax

```
fw ctl multik show_bypass_ports
```

## Example

```
[Expert@MyGW:0]# fw ctl multik show_bypass_ports
dynamic dispatcher bypass port list:
(9999,8888)
[Expert@MyGW:0]#
```

# fw ctl multik snd\_dist

## Description

Shows advanced information about distribution of connections by CoreXL SND instances.

## Syntax for IPv4

```
fw [-d] ctl multik snd_dist {-h | -d | -e | -i <Number> | -p | -r  
| -sn | -st | -t}
```

## Syntax for IPv6

```
fw6 [-d] ctl multik snd_dist {-h | -d | -e | -i <Number> | -p | -r  
| -sn | -st | -t}
```

## Parameters

| Parameter                                      | Description                                                                                                                                                                                                                                                          |
|------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>fw -d</code>                             | <p>Runs the command in debug mode.<br/>Use only if you troubleshoot the command itself.</p> <p>★ <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p> |
| <code>-h</code>                                | Shows the built-in help.                                                                                                                                                                                                                                             |
| <code>-e</code>                                | Enables the collection of the distribution information.                                                                                                                                                                                                              |
| <code>-p</code>                                | Prints the distribution information.                                                                                                                                                                                                                                 |
| <code>-r</code>                                | Restarts the collection of the distribution information (resets all counters).                                                                                                                                                                                       |
| <code>-d</code>                                | Disables the collection of the distribution information and deletes the collected information.                                                                                                                                                                       |
| <code>-i</code><br><code>&lt;Number&gt;</code> | Prints the specified number of 5-tuple iterations to the <code>dmesg</code> ring buffer.                                                                                                                                                                             |
| <code>-t</code>                                | <p>Toggles the debug - printing of 5-tuple iterations to the <code>dmesg</code> ring buffer. By default, this debug is disabled.</p> <p>Each time you run the command with this parameter, it changes the status of this debug.</p>                                  |
| <code>-st</code>                               | <p>Shows the status of the debug ("-t") in the text format:</p> <ul style="list-style-type: none"> <li>■ Snd_dist port debugs is not set</li> <li>■ Snd_dist port debugs is finished</li> <li>■ Snd_dist port debugs is running</li> </ul>                           |
| <code>-sn</code>                               | <p>Shows the status of the debug ("-t") in the numerical format.</p> <ul style="list-style-type: none"> <li>■ 0 - The debug is finished</li> <li>■ 1 - The debug is not set</li> <li>■ 2 - The debug is running</li> </ul>                                           |

## Example

```
[Expert@MyGW:0]# fw ctl multik snd_dist -p
Statistics is off
[Expert@MyGW:0]#

[Expert@MyGW:0]# fw ctl multik snd_dist -e
[Expert@MyGW:0]#

[Expert@MyGW:0]# fw ctl multik snd_dist -p
Requests via hash          5046
Requests via user hint     0
Total requests             5046
Number of active queues    1
Number of none instance cpus 1

Distribution by OPCODE:

=====

[Expert@MyGW:0]#

[Expert@MyGW:0]# fw ctl multik snd_dist -t
Snd_dist port debugs is on
[Expert@MyGW:0]#

[Expert@MyGW:0]# fw ctl multik snd_dist -st
Snd_dist port debugs is running
[Expert@MyGW:0]#

[Expert@MyGW:0]# fw ctl multik snd_dist -t
Snd_dist port debugs is off
[Expert@MyGW:0]#
```

# fw ctl multik stat

## Description

Shows information for each CoreXL Firewall instance.

## Syntax for IPv4

```
fw [-d] ctl multik stat
```

## Syntax for IPv6

```
fw6 [-d] ctl multik stat
```

## Information in the output

- The ID number of each CoreXL Firewall instance (numbers starts from zero).
- The state of each CoreXL Firewall instance.
- The ID number of CPU core, on which the CoreXL Firewall instance runs (numbers starts from the highest available CPU ID).
- The number of concurrent connections the CoreXL Firewall instance currently handles.
- The peak number of concurrent connections the CoreXL Firewall instance handled from the time it started.

## Parameters

| Parameter | Description                                                                                                                                                                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d        | <p>Runs the command in debug mode.<br/>Use only if you troubleshoot the command itself.</p> <p>★ <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p> |

## Example

```
[Expert@MyGW:0]# fw ctl multik stat
ID | Active | CPU | Connections | Peak
-----
0 | Yes | 7 | 5 | 21
1 | Yes | 6 | 3 | 23
2 | Yes | 5 | 5 | 25
3 | Yes | 4 | 4 | 21
4 | Yes | 3 | 5 | 21
5 | Yes | 2 | 5 | 20
[Expert@MyGW:0]#

[Expert@MyGW:0]# fw6 ctl multik stat
ID | Active | CPU | Connections | Peak
-----
0 | Yes | 7 | 0 | 4
1 | Yes | 6 | 0 | 4
[Expert@MyGW:0]#
```

# fw ctl multik start

## Description

Starts all CoreXL Firewall instances on-the-fly, if they were stopped with the *"fw ctl multik stop"* [on page 1753](#) command.

## Syntax for IPv4

```
fw ctl multik start
```

## Syntax for IPv6

```
fw6 ctl multik start
```

## Example

```
[Expert@MyGW:0]# fw ctl multik stat
ID | Active | CPU | Connections | Peak
-----
0 | No     | -   | 6 | 13
1 | No     | -   | 3 | 11
2 | No     | -   | 4 | 13
[Expert@MyGW:0]#
[Expert@MyGW:0]# fw ctl multik start
Instance 1 started (2 of 3 are active)
[Expert@MyGW:0]#
[Expert@MyGW:0]# fw ctl multik start
Instance 2 started (3 of 3 are active)
[Expert@MyGW:0]#
[Expert@MyGW:0]# fw ctl multik stat
ID | Active | CPU | Connections | Peak
-----
0 | Yes    | 3   | 5 | 13
1 | Yes    | 2   | 4 | 11
2 | Yes    | 1   | 4 | 13
[Expert@MyGW:0]#
[Expert@MyGW:0]# fw ctl multik start
All instances are already active
[Expert@MyGW:0]#
```

# fw ctl multik stop

## Description

Stops all CoreXL Firewall instances on-the-fly.

 **Important** - To start all CoreXL Firewall instances on-the-fly, run the *"fw ctl multik start" on page 1752* command.

## Syntax for IPv4

```
fw ctl multik stop
```

## Syntax for IPv6

```
fw6 ctl multik stop
```

## Example

```
[Expert@MyGW:0]# fw ctl multik stat
ID | Active | CPU | Connections | Peak
-----
0 | Yes    | 3   | 5           | 13
1 | Yes    | 2   | 4           | 11
2 | Yes    | 1   | 4           | 13
[Expert@MyGW:0]#
[Expert@MyGW:0]# fw ctl multik stop
Instance 2 stopped (2 of 3 are active)
[Expert@MyGW:0]#
[Expert@MyGW:0]# fw ctl multik stop
Instance 1 stopped (1 of 3 are active)
[Expert@MyGW:0]#
[Expert@MyGW:0]# fw ctl multik stat
ID | Active | CPU | Connections | Peak
-----
0 | Yes    | 3   | 4           | 13
1 | No     | -   | 3           | 11
2 | No     | -   | 7           | 13
[Expert@MyGW:0]#
[Expert@MyGW:0]# fw ctl multik stop
All instances are already inactive
[Expert@MyGW:0]#
[Expert@MyGW:0]# fw ctl multik stat
ID | Active | CPU | Connections | Peak
-----
0 | No     | -   | 6           | 13
1 | No     | -   | 3           | 11
2 | No     | -   | 4           | 13
[Expert@MyGW:0]#
```

# fw ctl multik utilize

## Description

Shows the CoreXL queue utilization for each CoreXL Firewall instance.

 **Note** - This command does not support VSX.

## Syntax for IPv4

```
fw ctl multik utilize
```

## Syntax for IPv6

```
fw6 ctl multik utilize
```

## Example

```
[Expert@MyGW:0]# fw ctl multik utilize
ID | Utilize(%) | Queue Elements
-----
0 | 1 | 30
1 | 0 | 10
2 | 0 | 17
[Expert@MyGW:0]#
[Expert@MyGW:0]# fw6 ctl multik utilize
ID | Utilize(%) | Queue Elements
-----
0 | 0 | 0
1 | 0 | 0
[Expert@MyGW:0]#
```

# fw ctl affinity

The "fw ctl affinity" and "fw6 ctl affinity" commands show and configure the CoreXL affinity settings for:

- Interfaces
- User-space processes
- CoreXL Firewall instances

In addition, see ["taskset\\_us\\_all" on page 1790](#).

# Running the 'fw ctl affinity -l' command in Gateway Mode

## Description

The "fw ctl affinity -l" (for IPv4) and "fw6 ctl affinity -l" (for IPv6) commands show the current CoreXL affinity settings on a Security Gateway for:

- Interfaces
- User-space processes
- CoreXL Firewall instances

## Syntax

- To see the built-in help:

```
fw ctl affinity
```

- To show all the existing affinities:

```
{fw | fw6} ctl affinity -l [-a] [-v] [-r] [-q]
```

- To show the affinity for a specified interface:

```
{fw | fw6} ctl affinity -l -i <Interface Name>
```

- To show the affinity for a specified CoreXL Firewall instance:

```
{fw | fw6} ctl affinity -l -k <CoreXL Firewall instance ID>
```

- To show the affinity for a specified user-space process by its PID:

```
fw ctl affinity -l -p <Process ID>
```

- To show the affinity for a specified user-space process by its name:

```
fw ctl affinity -l -n <Process Name>
```

- To show the number of system CPU cores allowed by the installed CoreXL license:

```
fw -d ctl affinity -corelicnum
```

**Parameters**

| Parameter                                           | Description                                                                                                               |
|-----------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>-i &lt;Interface Name&gt;</code>              | Shows the affinity for the specified interface.                                                                           |
| <code>-k &lt;CoreXL Firewall instance ID&gt;</code> | Shows the affinity for the specified CoreXL Firewall instance.                                                            |
| <code>-p &lt;Process ID&gt;</code>                  | Shows the affinity for the Check Point user-space process (for example: <i>fwd</i> , <i>vpnd</i> ) specified by its PID.  |
| <code>-n &lt;Process Name&gt;</code>                | Shows the affinity for the Check Point user-space process (for example: <i>fwd</i> , <i>vpnd</i> ) specified by its name. |
| <code>all</code>                                    | Shows the affinity for all CPU cores (numbers start from zero).                                                           |
| <code>&lt;CPU ID0&gt; ... &lt;CPU IDn&gt;</code>    | Shows the affinity for the specified CPU cores (numbers start from zero).                                                 |
| <code>-a</code>                                     | Shows all current CoreXL affinities.                                                                                      |
| <code>-v</code>                                     | Shows verbose output with IRQ numbers of interfaces.                                                                      |
| <code>-r</code>                                     | Shows the CoreXL affinities in reverse order.                                                                             |
| <code>-q</code>                                     | Suppresses the errors in the output.                                                                                      |

## Example 1

```
[Expert@MyGW:0]# fw ctl affinity -l
eth0: CPU 0
eth1: CPU 0
eth2: CPU 0
eth3: CPU 0
fw_0: CPU 7
fw_1: CPU 6
fw_2: CPU 5
fw_3: CPU 4
fw_4: CPU 3
fw_5: CPU 2
fwd: CPU 2 3 4 5 6 7
fgd50: CPU 2 3 4 5 6 7
status_proxy: CPU 2 3 4 5 6 7
rad: CPU 2 3 4 5 6 7
cpstat_monitor: CPU 2 3 4 5 6 7

[5363 4134733584]@MyGW[4 Apr 18:11:03] cpKeyTaskManager::~cpKeyTaskManager: called.
[Expert@MyGW:0]#
```

## Running the 'fw ctl affinity -l' command in VSX Mode

### Description

The "fw ctl affinity -l" (for IPv4) and fw6 ctl affinity -l (for IPv6) commands show the CoreXL affinity settings on a VSNext Security Group / Traditional VSX Gateway for:

- Interfaces
- User-space processes
- CoreXL Firewall instances

**Note** - Before running the "fw ctl affinity -l -x" commands, you must go to the context of the applicable Virtual Gateway / Traditional Virtual System / Traditional Virtual Router with the Gaia Clish command "set virtual-system <VSID>".

### Syntax

- To show the affinities in VSX mode (you can combine the optional parameters):

```
{fw | fw6} ctl affinity -l -x
    [-vsid <VSID ranges>]
    [-cpu <CPU ID ranges>]
    [-flags {e | k | t | n | h | o}]
```

- To show the number of system CPU cores allowed by the installed CoreXL license:

```
fw -d ctl affinity -corelicnum
```

## Parameters

| Parameter                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-vsid &lt;VSID ranges&gt;</code>      | <p>Shows the affinity for:</p> <ul style="list-style-type: none"> <li>▪ The specified single Virtual System (for example, <code>-vsid 7</code>)</li> <li>▪ The specified several Virtual Systems (for example, <code>-vsid 0-2 4</code>)</li> </ul> <p> <b>Important</b> - If you omit the <code>-vsid</code> parameter, the command runs in the current virtual context.</p>                                                                                                                                                                                                                                                                                                                                 |
| <code>&lt;CPU ID ranges&gt;</code>          | <p>Shows the affinity for:</p> <ul style="list-style-type: none"> <li>▪ The specified single CPU (for example, <code>-cpu 7</code>)</li> <li>▪ The specified several CPU cores (for example, <code>-cpu 0-2 4</code>)</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>-flags {e   k   t   n   h   o}</code> | <p>The <code>-flags</code> parameter requires at least one of these arguments:</p> <ul style="list-style-type: none"> <li>▪ <code>e</code> - Do not print the exception processes</li> <li>▪ <code>k</code> - Do not print the kernel threads</li> <li>▪ <code>t</code> - Print all process threads</li> <li>▪ <code>n</code> - Print the process name instead of the <code>/proc/&lt;PID&gt; /cmdline</code></li> <li>▪ <code>h</code> - Print the CPU mask in Hex format</li> <li>▪ <code>o</code> - Print the output into the file called <code>/tmp/affinity_list_output</code></li> </ul> <p> <b>Important</b> - You must specify multiple arguments together. For example: <code>-flags tn</code></p> |

**Example 1**

```
[Expert@VSX_GW:0]# fw ctl affinity -l -x -cpu 0
```

| PID  | VSID | CPU | SRC | V | KT | EXC | NAME |
|------|------|-----|-----|---|----|-----|------|
| 2    | 0    |     | 0   |   | K  |     |      |
| 3    | 0    |     | 0   |   | K  |     |      |

| 99   | 0    |     | 0   |   | K  |     |      |
| 278  | 0    |     | 0   |   | K  |     |      |
| 382  | 0    |     | 0   |   | K  |     |      |
| 674  | 0    |     | 0   |   | K  |     |      |
| 2195 | 0    |     | 0   |   | K  |     |      |
| 6348 | 0    |     | 0   |   | K  |     |      |
| 6378 | 0    |     | 0   |   | K  |     |      |

PID - represents the pid of the process

VSID - represents the virtual device id

CPU - represents the CPUs assigned to the specific process

SRC - represents the source configuration file of the process - (V)SID / (I)nstance / (P)rocess

V - represents validity, star means that the actual affinity is different than the configured affinity

KT - represents whether the process is a kernel thread

EXC - represents whether the process belongs to the process exception list (vsaffinity\_exception.conf)

```
[Expert@VSX_GW:0]#
```

**Example 2**

```
[Expert@VSX_GW:0]# fw ctl affinity -l -x -vsid 1
```

| PID   | VSID | CPU   | SRC | V | KT | EXC | NAME           |

# Running the 'fw ctl affinity -s' command in Gateway Mode

## Description

The "fw ctl affinity -s" command configures the CoreXL affinity settings on a Security Gateway for:

- Interfaces
- User-space processes
- CoreXL Firewall instances

**Note** - The command saves these configuration changes in the `$FWDIR/conf/fwaffinity.conf` configuration file.

## Syntax

- To see the built-in help:

```
fw ctl affinity
```

- To configure the affinity for a specified interface by its name:

```
fw ctl affinity -s -i <Interface Name>
all
<CPU ID0> [ <CPU ID1> ... <CPU IDn> ]
```

- To configure the affinity for a specified CoreXL Firewall instance:

```
fw ctl affinity -s -k <CoreXL Firewall instance ID>
all
<CPU ID0> [ <CPU ID1> ... <CPU IDn> ]
```

- To configure the affinity for a specified user-space process by its PID:

```
fw ctl affinity -s -p <Process ID>
all
<CPU ID0> [ <CPU ID1> ... <CPU IDn> ]
```

- To configure the affinity for a specified user-space process by its name:

```
fw ctl affinity -s -n <Process Name>
all
<CPU ID0> [ <CPU ID1> ... <CPU IDn> ]
```

## Parameters

| Parameter                                           | Description                                                                                                                                                                                                                                                                |
|-----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-i &lt;Interface Name&gt;</code>              | Configures the affinity for the specified interface.                                                                                                                                                                                                                       |
| <code>-k &lt;CoreXL Firewall instance ID&gt;</code> | Configures the affinity for the specified CoreXL Firewall instance.                                                                                                                                                                                                        |
| <code>-p &lt;Process ID&gt;</code>                  | Configures the affinity for the Check Point user-space process (for example: <i>fwd</i> , <i>vpnd</i> ) specified by its PID.                                                                                                                                              |
| <code>-n &lt;Process Name&gt;</code>                | Configures the affinity for the Check Point user-space process (for example: <i>fwd</i> , <i>vpnd</i> ) specified by its name.<br> <b>Important</b> - The process name is case-sensitive. |
| <code>all</code>                                    | Configures the affinity for all CPU cores (numbers start from zero).                                                                                                                                                                                                       |
| <code>&lt;CPU ID0&gt; ... &lt;CPU IDn&gt;</code>    | Configures the affinity for the specified CPU cores (numbers start from zero).                                                                                                                                                                                             |

### Example 1 - Affine the interface eth1 to the CPU core #1

```
[Expert@MyGW:0]# fw ctl affinity -s -i eth1 1
eth1: CPU 1 - set successfully
Multi-queue affinity was not changed. For More info, see sk113834.
[Expert@MyGW:0]#
```

### Example 2 - Affine the CoreXL Firewall instance #1 to the CPU core #2

```
[Expert@MyGW:0]# fw ctl affinity -s -k 1 2
fw_1: CPU 2 - set successfully
Multi-queue affinity was not changed. For More info, see sk113834.
[Expert@MyGW:0]#
```

### Example 3 - Affine the process CPD by its PID to the CPU core #2

```
[Expert@MyGW:0]# cpwd_admin list | egrep "PID|cpd"
APP      PID    STAT  #START  START_TIME      MON  COMMAND
CPD      6080   E      1       [13:46:27] 17/9/2018    Y    cpd
[Expert@MyGW:0]#
[Expert@MyGW:0]# fw ctl affinity -s -p 6080 2
Process 6080: CPU 2 - set successfully
Multi-queue affinity was not changed. For More info, see sk113834.
[Expert@MyGW:0]#
```

**Example 4 - Affine the process CPD by its name to the CPU core #2**

```
[Expert@MyGW:0]# fw ctl affinity -s -n cpd 2
cpd: CPU 2 - set successfully
Multi-queue affinity was not changed.  For More info, see sk113834.
[Expert@MyGW:0]#
```

# Running the 'fw ctl affinity -s' command in VSX Mode

## Description

The "fw ctl affinity -s" command configures the CoreXL affinity settings on a VSNext Security Group / Traditional VSX Gateway for:

- Interfaces
- User-space processes
- CoreXL Firewall instances

## Syntax

- To see the built-in help:

```
fw ctl affinity
```

- To configure the affinities of VSNext Virtual Gateways / Traditional VSX Virtual Systems:

```
fw ctl affinity -s -d [-vsid <VSID ranges> ] -cpu <CPU ID ranges>
```

- To configure the affinities of a specified user-space process:

```
fw ctl affinity -s -d -pname <Process Name> [-vsid <VSID ranges>]
    -cpu all
    -cpu <CPU ID ranges>
```

- To configure the affinities of specified FWK daemon instances (user-space Firewall):

```
fw ctl affinity -s -d -inst <Instances Ranges> -cpu <CPU ID ranges>
```

- To configure the affinities of all FWK instances (user-space Firewalls):

```
fw ctl affinity -s -d -fwkall <Number of CPUs>
```

- To reset the affinities to defaults:

```
fw ctl affinity
    -vsx_factory_defaults
    -vsx_factory_defaults_no_prompt
```

## Important

- The command saves these configuration changes in the `$FWDIR/conf/fwaffinity.conf` configuration file.
- When you configure affinity of an interface, it automatically configures the affinities of all other interfaces that share the same IRQ to the same CPU core.

## Parameters

| Parameter                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-vsid &lt;VSID ranges&gt;</code>      | <p>Configures the affinity for:</p> <ul style="list-style-type: none"> <li>■ One specified Virtual System.<br/>For example: <code>-vsid 7</code></li> <li>■ Several specified Virtual Systems.<br/>For example: <code>-vsid 0-2 4</code></li> </ul> <p> <b>Note</b> - If you omit the "-vsid" parameter, the command uses the current virtual context.</p> |
| <code>&lt;CPU ID ranges&gt;</code>          | <p>Configures the affinity to:</p> <ul style="list-style-type: none"> <li>■ One specified CPU core.<br/>For example: <code>-cpu 7</code></li> <li>■ Several specified CPU cores.<br/>For example: <code>-cpu 0-2 4</code></li> </ul> <p> <b>Important</b> - Numbers of CPU cores start from zero.</p>                                                    |
| <code>-pname &lt;Process Name&gt;</code>    | <p>Configures the affinity for the Check Point daemon specified by its name (for example: <code> fwd</code>, <code>vpnd</code>).</p> <p> <b>Important</b> - The process name is case-sensitive.</p>                                                                                                                                                      |
| <code>-inst &lt;Instances Ranges&gt;</code> | <p>Configures the affinity for:</p> <ul style="list-style-type: none"> <li>■ One specified FWK daemon instance.<br/>For example: <code>-inst 7</code></li> <li>■ Several specified FWK daemon instances.<br/>For example: <code>-inst 0 2 4</code></li> </ul>                                                                                                                                                                               |

| Parameter                                    | Description                                                                                                                                                                                                                                                                                                                                       |
|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-fwkall &lt;Number of CPUs&gt;</code>  | Configures the affinity for all running FWK daemon instances to the specified number of CPU cores.<br>If it is necessary to affine all running FWK daemon instances to all CPU cores, enter the number of all available CPU cores.                                                                                                                |
| <code>-vsx_factory_defaults</code>           | Deletes all existing affinity settings and creates the default affinity settings during the next reboot.<br> <b>Important</b> - Before this operation, the command prompts the user whether to proceed. You must reboot to complete the operation.               |
| <code>-vsx_factory_defaults_no_prompt</code> | Deletes all current affinity settings and creates the default affinity settings during the next reboot.<br> <b>Important</b> - Before this operation, the command does <b>not</b> prompt the user whether to proceed. You must reboot to complete the operation. |

### Example 1 - Affine the Virtual Devices #0,1,2,4,7,8 to the CPU cores #0,1,2,4

```
[Expert@VSX_GW:0]# fw ctl affinity -s -d -vsid 0-2 4 6-8 -cpu 0-2 4
VDevice 0-2 4 6-8 : CPU 0 1 2 4 - set successfully
Multi-queue affinity was not changed. For More info, see sk113834.
[Expert@VSX_GW:0]#
```

### Example 2 - Affine the process CPD by its name for Virtual Devices #0-12 to the CPU core #7

```
[Expert@VSX_GW:0]# fw ctl affinity -s -d -pname cpd -vsid 0-12 -cpu 7
VDevice 0-12 : CPU 7 - set successfully
Multi-queue affinity was not changed. For More info, see sk113834.
Warning: some of the VSIDs did not exist
[Expert@VSX_GW:0]#
```

### Example 3 - Affine the FWK daemon instances #0,2,4 to the CPU core #5

```
[Expert@VSX_GW:0]# fw ctl affinity -s -d -inst 0 2 4 -cpu 5
VDevice 0 2 4: CPU 5 - set successfully
Multi-queue affinity was not changed. For More info, see sk113834.
[Expert@VSX_GW:0]#
```

### Example 4 - Affine all FWK daemon instances to the last two CPU cores

```
[Expert@VSX_GW:0]# fw ctl affinity -s -d -fwkall 2
VDevice 0-2 : CPU 2 3 - set successfully
Multi-queue affinity was not changed. For More info, see sk113834.
[Expert@VSX_GW:0]#
```

**Example 5 - Affine all FWK daemon instances to all CPU cores**

```
[Expert@VSX_GW:0]# fw ctl affinity -s -d -fwkall 4
There are configured processes/FWK instances
(y) will override all currently configured affinity and erase the configuration files
(n) will set affinity only for unconfigured processes/threads
Do you want to override existing configurations (y/n) ? y
VDevice 0-2 : CPU all - set successfully
Multi-queue affinity was not changed. For More info, see sk113834.
[Expert@VSX_GW:0]#
```

# fw -i

## Description

By default, the ["fw" on page 1092](#) commands apply to the entire Security Gateway. The `fw` commands show aggregated information for all CoreXL Firewall instances. The `fw -i` commands apply to the specified CoreXL Firewall instance.

 **Important:**

- You can run this command in the Expert mode or in Gaia Clish (Gaia gClish on Scalable Platforms).
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.

## Syntax

```
fw -i <ID of CoreXL Firewall instance> <Command>
```

## Parameters

| Parameter                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;ID of CoreXL Firewall instance&gt;</code> | Specifies the ID of the CoreXL Firewall instance.<br>To see the available IDs, run the <a href="#">"fw ctl multik stat" on page 1750</a> command.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Example 1 - Show the Connections table for CoreXL Firewall instance #1

```
fw -i 1 tab -t connections
```

## Example 2 - Show various internal statistics for CoreXL Firewall instance #1

```
fw -i 1 ctl pstat
```

# fwboot bootconf

## Description

Configures boot security options.

### Notes:

- You must run this command from the Expert mode.
- The settings are saved in the `$FWDIR/boot/boot.conf` file.
  -  **Warning** - To avoid issues, do not edit the `$FWDIR/boot/boot.conf` file manually. Edit the file only with this command.
- Refer to these related commands:
  - ["fwboot corexl" on page 1304](#)
  - ["control\\_bootsec" on page 979](#)

## Syntax to show the current boot security options

```
[Expert@HostName:0]# $FWDIR/boot/fwboot bootconf
get_corexl
get_core_override
get_def
get_ipf
get_ipv6
get_kernnum
get_kern6num
```

## Syntax to configure the boot security options

```
[Expert@HostName:0]# $FWDIR/boot/fwboot bootconf
set_corexl {0 | 1}
set_core_override <number>
set_def [</path/filename>]
set_ipf {0 | 1}
set_ipv6 {0 | 1}
set_kernnum <number>
set_kern6num <number>
```

## Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

# fwboot corexl

## Description

Configures and monitors the CoreXL.

**Note** - The settings are saved in the `$FWDIR/boot/boot.conf` file.

**Warning** - To avoid issues, do not edit the `$FWDIR/boot/boot.conf` file manually. Edit the file only with this command.

## Syntax to show CoreXL configuration

```
[Expert@HostName:0]# $FWDIR/boot/fwboot corexl
core_count
curr_instance4_count
curr_instance6_count
def_instance4_count
def_instance6_count
eligible
installed
max_instance4_count
max_instances4_32bit
max_instances4_64bit
max_instance6_count
max_instances_count
max_instances_32bit
max_instances_64bit
min_instance_count
unsupported_features
```

## Syntax to configure CoreXL

### Important:

- The configuration commands are for Check Point use only. To configure CoreXL, use the **Check Point CoreXL** option in the ["cpconfig" on page 1002](#) menu.
- After all changes in CoreXL configuration on the Security Gateway, you must reboot it.
- In a Cluster, you must configure all the Cluster Members in the same way.

```
[Expert@HostName:0]# $FWDIR/boot/fwboot corexl
def_by_allowed [n]
default
[-v] disable
[-v] enable [n] [-6 k]
vmalloc_recalculate
```

## Parameters

| Parameter     | Description                                                                                                                                                                                                                                                                                                              |

# fwboot cpuid

## Description

Shows the number of available CPUs and CPU cores on this Security Gateway.

## Syntax

```
[Expert@HostName:0]# $FWDIR/boot/fwboot cpuid
{-h | -help | --help}
-c
--full
ht_aware
-n
--possible
```

## Parameters

| Parameter     | Description                                                                                                                                                                                                                                                    |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| No Parameters | <p>Shows the IDs of the available CPU cores on this Security Gateway.</p> <p><b>Example</b></p> <pre>[Expert@MyGW:0]# \$FWDIR/boot/fwboot cpuid 3 2 1 0 [Expert@MyGW:0]#</pre>                                                                                 |
| -c            | <p>Counts the number of available CPU cores on this Security Gateway. The command stores the returned number as its exit code.</p> <p><b>Example</b></p> <pre>[Expert@MyGW:0]# \$FWDIR/boot/fwboot cpuid -c [Expert@MyGW:0]# echo \$? 4 [Expert@MyGW:0]#</pre> |

| Parameter               | Description                                                                                                                                                                                                                                               |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--full</code>     | <p>Shows a full map of the available CPUs and CPU cores on this Security Gateway.</p> <p><b>Example</b></p> <pre>[Expert@MyGW:0]# \$FWDIR/boot/fwboot cpuid --full cpuid phys_id core_id thread_id 0 0 0 0 1 2 0 0 2 4 0 0 3 6 0 0 [Expert@MyGW:0]#</pre> |
| <code>ht_aware</code>   | <p>Shows the CPU cores in the order of their awareness of Hyper-Threading.</p> <p><b>Example</b></p> <pre>[Expert@MyGW:0]# \$FWDIR/boot/fwboot cpuid ht_aware 3 2 1 0 [Expert@MyGW:0]#</pre>                                                              |

| <code>--possible</code> | <p>Counts the number of possible CPU cores. The command stores the returned number as its exit code.</p> <p><b>Example</b></p> <pre>[Expert@MyGW:0]# \$FWDIR/boot/fwboot cpuid --possible [Expert@MyGW:0]# echo \$? 4 [Expert@MyGW:0]#</pre>              |

# fwboot ht

 **Important** - This command is obsolete and is not supported. To configure SMT (HyperThreading) feature, follow [sk93000](#).

# fwboot multik\_reg

## Description

Shows the internal memory address of the registration function for the specified CoreXL Firewall instance.

**Important** - This command is for Check Point use only.

**Note** - You must run this command from the Expert mode.

## Syntax

```
[Expert@HostName:0]# $FWDIR/boot/fwboot multik_reg <Number of  
CoreXL Firewall instance> {ipv4 | ipv6} [-d]
```

## Parameters

| Parameter                                         | Description                                              |
|---------------------------------------------------|----------------------------------------------------------|
| No Parameters                                     | Shows the built-in help with available parameters.       |
| <i>&lt;Number of CoreXL Firewall instance&gt;</i> | Specifies the ID number of the CoreXL Firewall instance. |
| ipv4                                              | Specifies to work with IPv4 CoreXL Firewall instances.   |
| ipv6                                              | Specifies to work with IPv6 CoreXL Firewall instances.   |
| -d                                                | Shows the decimal 64-bit address of the hook function.   |

## Example

```
[Expert@MyGW:0]# fw ctl multik stat
ID | Active | CPU | Connections | Peak
-----
0 | Yes    | 3   | 11          | 18
1 | Yes    | 2   | 12          | 18
2 | Yes    | 1   | 13          | 18
[Expert@MyGW:0]#

[Expert@MyGW:0]# $FWDIR/boot/fwboot multik_reg 0 ipv4
0
[Expert@MyGW:0]#

[Expert@MyGW:0]# $FWDIR/boot/fwboot multik_reg 1 ipv4
0xffffffff8a2a5690
[Expert@MyGW:0]#

[Expert@MyGW:0]# $FWDIR/boot/fwboot multik_reg 2 ipv4
0xffffffff8a2a5690
[Expert@MyGW:0]#
```

# fwboot post\_drv

## Description

Loads the Firewall driver for CoreXL during boot.

**Important:**

- This command is for Check Point use only.
- If you run this command, Security Gateway can block all traffic. In such case, you must connect to the Security Gateway over a console and restart Check Point services with the ["cpstop" on page 1043](#) and ["cpstart" on page 1032](#) commands. Alternatively, you can reboot the Security Gateway.

**Note** - You must run this command from the Expert mode.

## Syntax

```
[Expert@HostName:0]# $FWDIR/boot/fwboot post_drv {ipv4 | ipv6}
```

## Parameters

| Parameter     | Description                                        |
|---------------|----------------------------------------------------|
| No Parameters | Shows the built-in help with available parameters. |
| ipv4          | Loads the IPv4 Firewall driver for CoreXL.         |
| ipv6          | Loads the IPv6 Firewall driver for CoreXL.         |

# taskset\_us\_all

## Description

The script `$FWDIR/bin/taskset_us_all` configures the affinity of all running User Space processes to CPU cores.

- You can enter the required CPU cores either as a list of CPU core IDs, or as a CPU bitmask.
- You can configure the affinity User Space processes to CPU cores that run as CoreXL Firewall instances, as CoreXL SND, or all CPU cores.
- You can configure a list of User Space processes that this script must ignore.
- The script creates this log file: `$FWDIR/log/taskset_us_all.elg`

**Note** - You must run this command from the Expert mode.

## Related Information

["fw ctl affinity" on page 1755](#)

## Syntax

```
[Expert@HostName:0]# taskset_us_all
    --help}
    {-i | --instance} [<IDs of Instances>]
    {-l | --list} <IDs of CPU Cores>
        [--ignore_default]
        [--ignore_exe
"<ProcessName1>|<ProcessName2>|...|<ProcessNameN>"
        {-m | --mask} <CPU BitMask>
        {-s | --snd} [--no_zero]
```

On a Scalable Platform Security Group, you must run: `g_all taskset_us_all`  
`<parameters>`

## Parameters

# Multi-Queue Commands

For more information about Multi-Queue, see the [R82.10 Performance Tuning Administration Guide](#) - Chapter *Multi-Queue*.

# mq\_mng

You configure Multi-Queue on the command line in one of these shells:

- In the Expert mode
- In Gaia Clish
- In Gaia gClish on Scalable Platforms

## Multi-Queue Configuration in the Expert mode

### Description

The `mq_mng` utility shows and configures the Multi-Queue on supported interfaces.

## Syntax

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- You must run these commands in the Expert mode.
- On Scalable Platforms, you must connect to the applicable Security Group and use the "g\_all mq\_mng" commands.
- Change in the Multi-Queue mode can cause short packet loss.

#### ■ To see the built-in help

```
mq_mng {-h | --help}
```

#### ■ To show the existing Multi-Queue configuration:

```
mq_mng {-o | --show} [{-v | -vv}] [-a]
```

#### ■ To configure the Multi-Queue for the specified driver:

```
mq_mng {-s | --set-mode}
      auto
      manual
          {-i | --interface} <Names of Interfaces>
          {-c | --core} <IDs of CPU Cores>
      off
          [{-i | --interface} <Names of Interfaces>]
```

#### ■ To apply the existing Multi-Queue policy:

```
mq_mng {-r | --reconf}
```

## Parameters

| Parameter   | Description          |
|-------------|----------------------|
| -h   --help | Shows built-in help. |

| Parameter                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Set automatic Multi-Queue mode on all interfaces

```
mq_mng --set-mode auto
```

## Set manual Multi-Queue mode on the interfaces eth1 and eth2 to CPU cores 0, 1, 2, 4, 5, and 6

```
mq_mng -s manual -i eth1 eth2 -c 0-2 4-6
```

# Multi-Queue Configuration in Gaia Clish / Gaia gClish

## Syntax

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
  - You must run these commands in Gaia Clish / Gaia gClish.
  - On Scalable Platforms, you must connect to the applicable Security Group.
  - Change in the Multi-Queue mode can cause short packet loss.
- **To show the existing Multi-Queue configuration for the specified interface:**

```
show interface <Name of Interface> multi-queue [verbose]
```

- **To configure the Multi-Queue for the specified interface:**

```
set interface <Name of Interface> multi-queue
    auto
    manual core <IDs of CPU Cores that run CoreXL SND
Instances>
    off
```

## Parameters

| Parameter                        | Description                                                                                                                                                                               |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>&lt;Name of Interface&gt;</i> | Specifies the interface.                                                                                                                                                                  |
| verbose                          | Verbose output that also includes: <ul style="list-style-type: none"> <li>■ IRQ numbers for traffic queues</li> <li>■ Total number of RX and TX packets in traffic queues</li> </ul>      |
| auto                             | Configures the automatic Multi-Queue mode (this is the default). Multi-Queue automatically configures the affinity of the specified interface to CPU cores that run CoreXL SND Instances. |

| Parameter                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Examples

### Show Multi-Queue configuration on the interface eth2

```
MyGW> show interface eth2 multi-queue
```

```
Total 8 cores. Multiqueue 2 cores
```

| i/f  | type | state | config | cores |
|------|------|-------|--------|-------|
| eth2 | igb  | Up    | Auto   | 4,0   |

Note: The output does not include network interfaces that are currently in the down state.  
MyGW>

## Show Multi-Queue verbose configuration on the interface eth2

```
MyGW> show interface eth2 multi-queue verbose
```

```
Total 8 cores. Multiqueue 2 cores: 0,4
```

| i/f  | type       | state       | config | cores          |            |
|------|------------|-------------|--------|----------------|------------|
| eth2 | igb        | Up          | Auto   | 4 (62), 0 (79) |            |
| core | interfaces | queue       | irq    | rx packets     | tx packets |
| 0    | eth2       | eth2-TxRx-1 | 79     | 212            | 80         |
| 4    | eth2       | eth2-TxRx-0 | 62     | 16232          | 18901      |

```
MyGW>
```

## Set automatic Multi-Queue mode on the interface eth2

```
set interface eth2 multi-queue auto
```

## Set manual Multi-Queue mode on the interface eth2 to CPU cores 0, 1, 2, 4, 5, and 6

```
set interface eth2 multi-queue manual core 0-2,4-6
```

# Identity Awareness Commands

For more information about Identity Awareness, see the [R82.10 Identity Awareness Administration Guide](#).

These terms are used in the CLI commands:

| Term         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PDP</b>   | Identity Awareness Policy Decision Point.<br>This is an Identity Awareness Security Gateway, which is responsible to collect and share identities.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>PEP</b>   | Identity Awareness Policy Enforcement Point.<br>This is an Identity Awareness Security Gateway, which is responsible to enforce network access restrictions.<br>It makes its decisions based on identity data it collected from the <b>PDP</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>ADLOG</b> | The module responsible for the acquisition of identities of entities (users or computers) from the Active Directory.<br>The <code>adlog</code> runs on: <ul style="list-style-type: none"> <li>■ An Identity Awareness Security Gateway, for which you enabled the AD Query.<br/>The AD Query serves the Identity Awareness Software Blade, which enforces the policy and logs identities.</li> <li>■ A Log Server. The <code>adlog</code> logs identities.</li> </ul> <p>The <code>adlog</code> is the command line process used to control and monitor the ADLOG feature.<br/>The command line tool helps control users' statuses, as well as troubleshoot and monitor the system.</p> |

The **PEP** and **PDP** processes are key components of the system. Through them, administrators control user access and network protection.

## Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vsenv <VS ID>`).

# adlog

## Description

Provides commands to control and monitor the AD Query (formerly AD Log) process.

## Syntax

- When the `adlog` runs on a Security Gateway, the AD Query serves the Identity Awareness Software Blade, which enforces policy and logs identities.

In this case, the command syntax is:

```
adlog a <parameter> [<option>]
```

- When the `adlog` runs on a Log Server with Identity Logging enabled, it logs identities.

In this case, the command syntax is:

```
adlog l <parameter> [<option>]
```

**Note** - Parameters for the "adlog a" and "adlog l" commands are identical.

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vsenv <VS ID>`).

## Parameters

| Parameter                       | Description                                                                                                                                                                                                                 |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| No Parameters                   | Displays available options for this command and exits.                                                                                                                                                                      |
| a<br>or<br>l                    | Sets the working mode: <ul style="list-style-type: none"> <li><code>adlog a</code> - If you use the AD Query for Identity Awareness.</li> <li><code>adlog l</code> - If you use a Log Server (Identity Logging).</li> </ul> |
| control <parameter><br><option> | Sends control commands to the AD Query.<br>See <a href="#">"adlog control" on page 1808</a> .                                                                                                                               |

| Parameter                     | Description                                                                                                                                                                                          |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dc                            | Shows the status of a connection to the AD domain controller.<br>See <a href="#">"adlog dc" on page 1810</a> .                                                                                       |
| debug <parameter>             | Enables and disables the adlog debug output.<br>See <a href="#">"adlog debug" on page 1811</a> .                                                                                                     |
| query <parameter><br><option> | Shows the database of identities acquired by the AD Query, according to the specified filter.<br>See <a href="#">"adlog query" on page 1812</a> .                                                    |
| statistics                    | Shows statistics about NT Event logs received by adlog, for each IP address and total.<br>Also shows the number of identified IP addresses.<br>See <a href="#">"adlog statistics" on page 1813</a> . |

# adlog control

## Description

Sends control commands to the AD Query (formerly AD Log).

## Syntax

```
adlog {a | l} control
    muh <options>
    reconf
    srv_accounts <options>
    stop
```

 **Important:**

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vsenv <VS ID>`).

## Parameters

| Parameter                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>muh &lt;options&gt;</code> | <p>Manages the list of Multi-User Hosts.</p> <p>The available <code>&lt;options&gt;</code> are:</p> <ul style="list-style-type: none"><li>▪ Show all known Multi-User Hosts (MUHs):<div>adlog {a   l} control muh show</div></li><li>▪ Add an IP address as a Multi-User Host (MUH):<div>adlog {a   l} control muh mark</div></li><li>▪ Removes an IP address from the list of Multi-User Hosts (MUHs):<div>adlog {a   l} control muh unmark</div></li></ul> |
| <code>reconf</code>              | <p>Sends a reconfiguration command to the AD Query.</p> <p>Resets the policy configuration to the one defined in SmartConsole.</p>                                                                                                                                                                                                                                                                                                                           |

| Parameter                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

# adlog dc

## Description

Shows the status of a connection to the Active Directory Domain Controller.

## Syntax

```
adlog a dc
```

```
adlog l dc
```

### Important:

- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vse nv <VS ID>`).

# adlog debug

## Description

Enables and disables the `adlog` debug output.

| Feature                                  | Output Debug File                 |
|------------------------------------------|-----------------------------------|
| Identity Awareness on a Security Gateway | <code>\$FWDIR/log/pdpc.elg</code> |
| Identity Logging on a Log Server         | <code>\$FWDIR/log/fwd.elg</code>  |

## Syntax

```
adlog {a | l} debug
      extended
      mode
      off
      on
```

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vseenv <VS ID>`).

## Parameters

| Parameter             | Description                                        |
|-----------------------|----------------------------------------------------|
| <code>extended</code> | Turns on the debug and adds extended debug topics. |
| <code>mode</code>     | Shows the debug status ("on", or "off").           |
| <code>off</code>      | Turns off the debug.                               |
| <code>on</code>       | Turns on the debug.                                |

# adlog query

## Description

Shows the database of identities acquired by the AD Query (formerly AD Log), according to the specified filter.

## Syntax

```
adlog {a | l} query
    all
    ip <IP Address>
    machine <Computer Name>
    string <String>
    user <Username>
```

### Important:

- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vsenv <VS ID>`).

## Parameters

| Parameter               | Description                                                     |
|-------------------------|-----------------------------------------------------------------|
| all                     | No filter. Shows the entire identity database.                  |
| ip <IP Address>         | Filters identities that relate to the specified IP address.     |
| machine <Computer Name> | Filters identity mappings based on the specified computer name. |
| string <String>         | Filters identity mappings based on the specified text string.   |
| user <Username>         | Filters identity mappings based on the specified user.          |

## Example - Show the entry that contains the string "jo" in the user name

```
adlog a query user jo
```

# adlog statistics

## Description

Shows statistics about NT Event logs received by `adlog`, for each IP address and total.

Also shows the number of identified IP addresses.

## Syntax

```
adlog a statistics
```

```
adlog l statistics
```

### Important:

- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vseenv <VS ID>`).

# adlogconfig

## Description

Configures advanced AD Query (formerly AD Log) settings through a text menu.

Each setting has a default value.

If you change the default value or manually configure the default value, then the change is saved in the `$FWDIR/conf/ad_log_override.C` file.

## Syntax

- On a Security Gateway / each Cluster Member / Security Group, run:

```
adlogconfig a
```

- On a Log Server with Identity Logging enabled, run:

```
adlogconfig l
```

 **Note** - Menu options in the "adlogconfig a" and "adlogconfig l" commands are identical.

 **Important:**

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vsenv <VS ID>`).

## Default Output

```

[ ] Override default AD Query configuration
  [ ] Enable AD Query
    [ ] Create logs also for logoff events
    [ ] Create logs with timestamp from AD
        Timeout for username-and-IP association (minutes,
0=disabled): 0
        Interval for fetching Full Name for known users (days,
0=disabled): 0
        Hour of the day for fetching Full Name for known users
(0=disabled): 0
        Threshold for Multi-User Host detection (logged in
users): 7
        Timeout for revoked users on single user hosts
(seconds): 14400
    [X] Mark hosts as Multi-User Hosts after X users logged in
        Timeout for Multi-User Host mark (seconds): 2592000
        Threshold for Service Account detection (logins): 10
    [ ] Automatically exclude Service Accounts
[ ] Override default parameters for AD communication
    Interval between AD queries for login events (seconds,
0=disabled): 0
    Max returned objects for each AD query data chunk
(0=unlimited): 0
[ ] Ignore login events received from other AD Domains
[X] Do not check if AD password expired
[ ] AD authentication mode
    [ ] Use NTLMv1
    [X] Use NTLMv2
[ ] Assume that all hosts are for single users
[ ] Ignore hostnames of users' computers
[X] Use automatic AD updates about LDAP groups membership
    Timeout for accumulating LDAP group updates (seconds):
10
    [X] Use LDAP group updates about users only
[ ] Prefer IPv6 addresses for Domain Controllers
[1] WMI query Type

```

```
=====
```

- 1 - Use / Do not use the AD Query 'override' file
- 2 - Enable / Disable the AD Query feature
- 3 - Create logs also for logoff events
- 4 - Create logs with timestamp from AD
- 5 - Timeout for username-and-IP association

- 6 - Query interval (in days) for fetching Full Name for known users
- 7 - Query hour of the day for fetching Full Name for known users
- 8 - Add AD Domain and its Domain Controllers
- 9 - Delete AD Domain and its Domain Controllers
- 10 - Reconfigure AD username
- 11 - Reconfigure AD Password
- 12 - Reconfigure AD Domain Controllers
- 13 - Number of logged in users for Multi-User Host detection
- 14 - Timeout for revoked users on single user hosts
- 15 - Mark / Do not mark hosts as Multi-User Hosts after X users logged in
- 16 - Timeout for Multi-User Host mark
- 17 - Override / Do not override parameters for communication with AD
- 18 - Interval between AD queries for login events
- 19 - Max returned objects per data chunk in each AD query for login events
- 20 - Check / Do not check if AD password expired (every 24 hrs)
- 21 - AD authentication mode - NTLMv1 / NTLMv2
- 22 - Assume / Do not assume that all hosts are for single users
- 23 - Threshold for Service Account detection
- 24 - Ignore / Do not ignore login events received from other AD Domains
- 25 - Exclude / Do not exclude Service Accounts automatically from user association
- 26 - Ignore / Do not ignore hostnames of users' computers
- 27 - Ignore / Do not ignore automatic AD updates about LDAP groups membership
- 28 - Timeout for accumulating LDAP group updates
- 29 - Use LDAP group updates about users only / about all changes
- 30 - Prefer / Do not prefer IPv6 addresses for Domain Controllers
- 31 - WMI query type
- 32 - Exit without saving
- 33 - Save configuration and exit

## Explanations for the bottom section of the menu

### 1 - Use / Do not use the AD Query 'override' file

#### Description:

Specifies whether to use the non-default settings from the `$FWDIR/conf/ad_log_override.C` file that you configure in this menu.

Default: disabled (does not use this file).

#### Configuration in the `$FWDIR/conf/ad_log_override.C` file:

| Item                       | Value                          |
|----------------------------|--------------------------------|
| Parameter type             | Boolean                        |
| Default implicit value     | <code>:Override (false)</code> |
| Non-Default explicit value | <code>:Override (true)</code>  |

### 2 - Enable / Disable the AD Query feature

#### Description:

Specifies whether to use the non-default AD Query (formerly AD Log) settings that you configure in this menu.

Default: disabled (does not use the values configured in the `$FWDIR/conf/ad_log_override.C` file).

#### Configuration in the `$FWDIR/conf/ad_log_override.C` file:

| Item                       | Value                             |
|----------------------------|-----------------------------------|
| Parameter type             | Boolean                           |
| Default implicit value     | <code>:EnableAdLog (false)</code> |
| Non-Default explicit value | <code>:EnableAdLog (true)</code>  |

### 3 - Create logs also for logoff events

**Description:**

Specifies whether the Identity Awareness Gateway needs to create a log for a logoff event in addition to a login event.

Default: disabled (does not create logs for logoff events).

Configuration in the *\$FWDIR/conf/ad\_log\_override.C* file:

| Item                       | Value                                           |
|----------------------------|-------------------------------------------------|
| Parameter type             | Boolean                                         |
| Default implicit value     | <code>:EnableLogForLoginOrLogoff (false)</code> |
| Non-Default explicit value | <code>:EnableLogForLoginOrLogoff (true)</code>  |

### 4 - Create logs with timestamp from AD

**Description:**

Specifies whether to use the time when the event was created on the Active Directory (original creation time) instead of the time when the event is handled on the Identity Awareness Gateway.

Default: disabled (does not use the timestamp from the Active Directory).

Configuration in the *\$FWDIR/conf/ad\_log\_override.C* file:

| Item                       | Value                                            |
|----------------------------|--------------------------------------------------|
| Parameter type             | Boolean                                          |
| Default implicit value     | <code>:UseLogOriginalCreationTime (false)</code> |
| Non-Default explicit value | <code>:UseLogOriginalCreationTime (true)</code>  |

## 5 - Timeout for username-and-IP association

### Description:

Specifies the timeout (in minutes) for the association of the user's IP address and the username.

Default: 0 (disabled).

Configuration in the *\$FWDIR/conf/ad\_log\_override.C* file:

| Item                       | Value                                |
|----------------------------|--------------------------------------|
| Parameter type             | Integer                              |
| Default implicit value     | :AssociationTimeout (0x0)            |
| Non-Default explicit value | :AssociationTimeout (0x<Hex Number>) |

## 6 - Query interval (in days) for fetching Full Name for known users

### Description:

Specifies the interval (in days) for fetching the full name of the known users from Active Directory.

Default: 0 days (disabled).

Configuration in the *\$FWDIR/conf/ad\_log\_override.C* file:

| Item                       | Value                                   |
|----------------------------|-----------------------------------------|
| Parameter type             | Integer                                 |
| Default implicit value     | :FullNameQueryInterval (0x0)            |
| Non-Default explicit value | :FullNameQueryInterval (0x<Hex Number>) |

## 7 - Query hour of the day for fetching Full Name for known users

### Description:

Specifies the round hour of the day for fetching the full name of the known users from Active Directory.

Default: 0 days (disabled).

Configuration in the *\$FWDIR/conf/ad\_log\_override.C* file:

| Item                       | Value                               |
|----------------------------|-------------------------------------|
| Parameter type             | Integer                             |
| Default implicit value     | :FullNameFetchHour (0x0)            |
| Non-Default explicit value | :FullNameFetchHour (0x<Hex Number>) |

## 8 - Add AD Domain and its Domain Controllers

### Description:

Specifies the Active Directory Domain, Domain Controllers, Username, and Password.

Configuration in the *\$FWDIR/conf/ad\_log\_override.C* file:

| Item           | Value  |
|----------------|--------|
| Parameter type | String |

### Example:

```
:Domains (
    : (
        :DomainName (example.com)
        :Username (admin)
        :Password (<Hashed Password>)
        :DomainControllers (
            : (dc1.example.com)
            : (dc2.example.com)
        )
    )
)
```

## 9 - Delete AD Domain and its Domain Controllers

### Description:

In the `$FWDIR/conf/ad_log_override.C` file, deletes the Active Directory Domain and its Domain Controllers you configured with this option:

*["8 - Add AD Domain and its Domain Controllers" on the previous page](#)*

## 10 - Reconfigure AD username

### Description:

In the `$FWDIR/conf/ad_log_override.C` file, overwrites the Active Directory Domain username you configured with this option:

*["8 - Add AD Domain and its Domain Controllers" on the previous page](#)*

## 11 - Reconfigure AD Password

### Description:

In the `$FWDIR/conf/ad_log_override.C` file, overwrites the Active Directory Domain password you configured with this option:

*["8 - Add AD Domain and its Domain Controllers" on the previous page](#)*

## 12 - Reconfigure AD Domain Controllers

### Description:

In the `$FWDIR/conf/ad_log_override.C` file, overwrites the Active Directory Domain Controllers you configured with this option:

*["8 - Add AD Domain and its Domain Controllers" on the previous page](#)*

### 13 - Number of logged in users for Multi-User Host detection

#### Description:

Specifies the number of logged on users from the same IP address, after which this IP address is considered a Multi-User Host (MUH) computer.

Default: 7 users.

Configuration in the *\$FWDIR/conf/ad\_log\_override.C* file:

| Item                       | Value                                |
|----------------------------|--------------------------------------|
| Parameter type             | Integer                              |
| Default implicit value     | :MultiUserThreshold (0x7)            |
| Non-Default explicit value | :MultiUserThreshold (0x<Hex Number>) |

### 14 - Timeout for revoked users on single user hosts

#### Description:

 **Note** - Applies only when you enable this option:  
["22 - Assume / Do not assume that all hosts are for single users" on page 1830](#)

Specifies the time interval, during which the Identity Awareness Gateway ignores an association of a previously logged in user on a computer to a new IP address.

This means that during this interval, the previously logged in users cannot pass traffic through the Identity Awareness Gateway if they log in on a different computer.

Default: 14400 seconds (240 minutes).

Configuration in the *\$FWDIR/conf/ad\_log\_override.C* file:

| Item                       | Value                                |
|----------------------------|--------------------------------------|
| Parameter type             | Integer                              |
| Default implicit value     | :RevokedUserTimeout (0x3840)         |
| Non-Default explicit value | :RevokedUserTimeout (0x<Hex Number>) |

## 15 - Mark / Do not mark hosts as Multi-User Hosts after X users logged in

### Description:

If you disable this option, then the Identity Awareness Gateway does not mark a source IP address as a Multi-User Host (MUH) computer when there are more than X users logged in on the computer.

"X" is the value you configure with the option ["13 - Number of logged in users for Multi-User Host detection" on the previous page](#).

Default: enabled (marks a source IP address as a Multi-User Host).

Configuration in the `$FWDIR/conf/ad_log_override.C` file:

| Item                       | Value                                           |
|----------------------------|-------------------------------------------------|
| Parameter type             | Boolean                                         |
| Default implicit value     | <code>:DisableMultiUserPersistDB (false)</code> |
| Non-Default explicit value | <code>:DisableMultiUserPersistDB (true)</code>  |

## 16 - Timeout for Multi-User Host mark

### Description:

Specifies the time interval, during which the Identity Awareness Gateway keeps a source IP address marked as Multi-User Host (MUH) computer when there are more than X users logged in on the computer.

"X" is the value you configure with the option ["13 - Number of logged in users for Multi-User Host detection" on the previous page](#).

Default: 2592000 seconds (43200 minutes = 720 hours = 30 days)

Configuration in the `$FWDIR/conf/ad_log_override.C` file:

| Item                       | Value                                                               |
|----------------------------|---------------------------------------------------------------------|
| Parameter type             | Integer                                                             |
| Default implicit value     | <code>:MultiUserPersistMachineTimeout (0x278d00)</code>             |
| Non-Default explicit value | <code>:MultiUserPersistMachineTimeout (0x&lt;Hex Number&gt;)</code> |

## 17 - Override / Do not override parameters for communication with AD

### Description:

Specifies whether to use the settings configured with these options:

- ["18 - Interval between AD queries for login events" below](#)
- ["19 - Max returned objects per data chunk in each AD query for login events" on the next page](#)

Default: disabled (uses the default parameters).

Configuration in the `$FWDIR/conf/ad_log_override.C` file:

| Item                       | Value                                  |
|----------------------------|----------------------------------------|
| Parameter type             | Boolean                                |
| Default implicit value     | <code>:QueryWhitinCount (false)</code> |
| Non-Default explicit value | <code>:QueryWhitinCount (true)</code>  |

## 18 - Interval between AD queries for login events

### Description:

How frequently (in seconds) the Identity Awareness Gateway asks the Active Directory for login events.

Default: 1 second.

Configuration in the `$FWDIR/conf/ad_log_override.C` file:

| Item                       | Value                                                      |
|----------------------------|------------------------------------------------------------|
| Parameter type             | Integer                                                    |
| Default implicit value     | <code>:FullNameQueryInterval (0x0)</code>                  |
| Non-Default explicit value | <code>:FullNameQueryInterval (0x&lt;Hex Number&gt;)</code> |

## 19 - Max returned objects per data chunk in each AD query for login events

### Description:

When the Identity Awareness Gateway asks the Active Directory for login events, this controls the number of returned users in each data chunk

Default: 100 users per data chunk.

Configuration in the *\$FWDIR/conf/ad\_log\_override.C* file:

| Item                       | Value                                                        |
|----------------------------|--------------------------------------------------------------|
| Parameter type             | Integer                                                      |
| Default implicit value     | <code>:QueryMaxReturnedObjects (0x64)</code>                 |
| Non-Default explicit value | <code>:QueryMaxReturnedObjects (0x&lt;Hex Number&gt;)</code> |

## 20 - Check / Do not check if AD password expired (every 24 hrs)

### Description:

Specifies whether to check (every 24 hours) if the password had expired for the account the Identity Awareness Gateway uses to connect to the Active Directory to query for new login events.

Default: disabled (does not check).

Configuration in the *\$FWDIR/conf/ad\_log\_override.C* file:

| Item                       | Value                                     |
|----------------------------|-------------------------------------------|
| Parameter type             | Boolean                                   |
| Default implicit value     | <code>:DisablePassExpCheck (true)</code>  |
| Non-Default explicit value | <code>:DisablePassExpCheck (false)</code> |

## 21 - AD authentication mode - NTLMv1 / NTLMv2

### Description:

Controls which authentication mode to use when connecting to Active Directory - NTLMv1 or NTLMv2.

Default: NTLMv2.

Configuration in the *\$FWDIR/conf/ad\_log\_override.C* file:

| Item                       | Value              |
|----------------------------|--------------------|
| Parameter type             | Boolean            |
| Default implicit value     | :UseNTLMv2 (true)  |
| Non-Default explicit value | :UseNTLMv2 (false) |

## 22 - Assume / Do not assume that all hosts are for single users

### Description:

Specifies whether to keep only one association between the source IP address and the username.

If another user logs in on the same computer, then the new username replaces the previous username in the Identity Awareness Gateway.

Default: disabled (does not assume).

Configuration in the *\$FWDIR/conf/ad\_log\_override.C* file:

| Item                       | Value                         |
|----------------------------|-------------------------------|
| Parameter type             | Boolean                       |
| Default implicit value     | :SingleUserAssumption (false) |
| Non-Default explicit value | :SingleUserAssumption (true)  |

## 23 - Threshold for Service Account detection

### Description:

Specifies the number of a user logins from different IP addresses to identify the user as a Service Account.

Default: 10 logins.

Configuration in the *\$FWDIR/conf/ad\_log\_override.C* file:

| Item                       | Value                                     |
|----------------------------|-------------------------------------------|
| Parameter type             | Integer                                   |
| Default implicit value     | :ServiceAccountThreshold (0xa)            |
| Non-Default explicit value | :ServiceAccountThreshold (0x<Hex Number>) |

## 24 - Ignore / Do not ignore login events received from other AD Domains

### Description:

Specifies whether to ignore login events received from different domains than configured for AD Query.

Default: disabled (does not ignore).

Configuration in the *\$FWDIR/conf/ad\_log\_override.C* file:

| Item                       | Value                           |
|----------------------------|---------------------------------|
| Parameter type             | Boolean                         |
| Default implicit value     | :IgnoreDifferentDomains (false) |
| Non-Default explicit value | :IgnoreDifferentDomains (true)  |

## 25 - Exclude / Do not exclude Service Accounts automatically from user association

### Description:

Controls whether to exclude Service Accounts from user association.

Default: disabled (does not exclude).

Configuration in the *\$FWDIR/conf/ad\_log\_override.C* file:

| Item                       | Value                                        |
|----------------------------|----------------------------------------------|
| Parameter type             | Boolean                                      |
| Default implicit value     | <code>:ExcludeServiceAccounts (false)</code> |
| Non-Default explicit value | <code>:ExcludeServiceAccounts (true)</code>  |

## 26 - Ignore / Do not ignore hostnames of users' computers

### Description:

Controls whether to ignore the hostname of the computer, on which a user logged in.

Default: disabled (does not ignore).

Configuration in the *\$FWDIR/conf/ad\_log\_override.C* file:

| Item                       | Value                                    |
|----------------------------|------------------------------------------|
| Parameter type             | Boolean                                  |
| Default implicit value     | <code>:DontReportMachines (false)</code> |
| Non-Default explicit value | <code>:DontReportMachines (true)</code>  |

## 27 - Ignore / Do not ignore automatic AD updates about LDAP groups membership

### Description:

Controls whether to ignore the automatic Active Directory updates about LDAP groups membership.

Default: enabled (does not ignore).

Configuration in the *\$FWDIR/conf/ad\_log\_override.C* file:

| Item                       | Value                                        |
|----------------------------|----------------------------------------------|
| Parameter type             | Boolean                                      |
| Default implicit value     | <code>:LdapGroupsUpdateEnable (true)</code>  |
| Non-Default explicit value | <code>:LdapGroupsUpdateEnable (false)</code> |

## 28 - Timeout for accumulating LDAP group updates

### Description:

 **Note** - Applies only when you enable this option:  
*"27 - Ignore / Do not ignore automatic AD updates about LDAP groups membership" above*

Controls the amount of time (in seconds) during which the Identity Awareness Gateway accumulates LDAP group notifications before recalculating the users' access.

Default: 10 seconds.

Configuration in the *\$FWDIR/conf/ad\_log\_override.C* file:

| Item                       | Value                                                      |
|----------------------------|------------------------------------------------------------|
| Parameter type             | Integer                                                    |
| Default implicit value     | <code>:LdapGroupsUpdateDelay (0x0)</code>                  |
| Non-Default explicit value | <code>:LdapGroupsUpdateDelay (0x&lt;Hex Number&gt;)</code> |

## 29 - Use LDAP group updates about users only / about all changes

### Description:

 **Warning** - If you disable the default behavior, the CPU load on the Identity Awareness Gateway increases significantly.

 **Note** - Applies only when you enable this option:  
["27 - Ignore / Do not ignore automatic AD updates about LDAP groups membership" on the previous page](#)

Controls whether to process LDAP group notifications only for changes related to users, or process all LDAP group notifications.

Default: enabled (uses notifications only for changes related to users).

### Configuration in the `$FWDIR/conf/ad_log_override.C` file:

| Item                       | Value                                     |
|----------------------------|-------------------------------------------|
| Parameter type             | Boolean                                   |
| Default implicit value     | <code>:LdapGroupsUpdateAll (false)</code> |
| Non-Default explicit value | <code>:LdapGroupsUpdateAll (true)</code>  |

## 30 - Prefer / Do not prefer IPv6 addresses for Domain Controllers

### Description:

Specifies whether to use IPv6 addresses if a DNS query for the specified domain controllers returns IPv4 addresses and IPv6 addresses.

Default: disabled (does not prefer).

### Configuration in the `$FWDIR/conf/ad_log_override.C` file:

| Item                       | Value                                       |
|----------------------------|---------------------------------------------|
| Parameter type             | Boolean                                     |
| Default implicit value     | <code>:PreferIPv6DCAddresses (false)</code> |
| Non-Default explicit value | <code>:PreferIPv6DCAddresses (true)</code>  |

## 31 - WMI query type

**Description:**

Specifies the WMI Query Type for Active Directory.

Default: 1.

| WMI Query Type ID | WMI Query Name                               | WMI Query Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1                 | Admin query                                  | Regular Query.<br>Includes reading forwarded security events logs.<br>Requires the account to be a member of the "Server Operators" group.                                                                                                                                                                                                                                                                                                                                                                                                |
| 2                 | Fallback from Admin query to non-Admin query | Fallback Configuration.<br>Identity Awareness Gateway will first try the default regular query, and in case it fails following a WMI permissions error, it will try the Non-Admin query (reduced query).                                                                                                                                                                                                                                                                                                                                  |
| 3                 | Non-Admin query                              | Reduced Query.<br>Identity Awareness Gateway will always use the query without forwarded events.<br>Membership in the "Server Operators" group is not needed.<br> <b>Important</b> - Using the reduced query in Active Directory environments, in which forwarding of security event logs between Domain Controllers is configured, might lead to missing relevant security event logs. As a result, some users and/or machines may not be recognized. |

Configuration in the `$FWDIR/conf/ad_log_override.C` file:

| Item                       | Value                          |
|----------------------------|--------------------------------|
| Parameter type             | Integer                        |
| Default implicit value     | :WmiQueryType (0x1)            |
| Non-Default explicit value | :WmiQueryType (0x<Hex Number>) |

**32 - Exit without saving****Description:**

Exits from this menu without saving any changes you made.

**33 - Save configuration and exit****Description:**

Saving the changes you made and exits from this menu.

# cpview

## Overview of CPView

### Description

CPView is a text based built-in utility on a Check Point computer.

CPView Utility shows statistical data that contain both general system information (CPU, Memory, Disk space) and information for different Software Blades (only on a Security Gateway / ClusterXL / Scalable Platform Security Group).

The CPView continuously updates the data in easy to access views.

On a Security Gateway / ClusterXL / Scalable Platform Security Group, you can use this statistical data to monitor the performance.

For more information, see [sk101878](#).

### Syntax

```
cpview --help
```

## CPView User Interface

The CPView user interface has three sections:

| Section    | Description                                                                                                                                    |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| Header     | This view shows the time the statistics in the third view are collected. It updates when you refresh the statistics.                           |
| Navigation | This menu bar is interactive. Move between menus with the arrow keys and mouse.<br>A menu can have sub-menus and they show under the menu bar. |
| View       | This view shows the statistics collected in that view. These statistics update at the refresh rate.                                            |

## Using CPView

Use these keys to navigate the CPView:

| Key        | Description                                                                                                                 |
|------------|-----------------------------------------------------------------------------------------------------------------------------|
| Arrow keys | Moves between menus and views. Scrolls in a view.                                                                           |
| Home       | Returns to the <b>Overview</b> view.                                                                                        |
| Enter      | Changes to the <b>View Mode</b> .<br>On a menu with sub-menus, the <b>Enter</b> key moves you to the lowest level sub-menu. |
| Esc        | Returns to the <b>Menu Mode</b> .                                                                                           |
| Q          | Quits CPView.                                                                                                               |

Use these keys to change CPView interface options:

| Key | Description                                                                                          |
|-----|------------------------------------------------------------------------------------------------------|
| R   | Opens a window where you can change the refresh rate.<br>The default refresh rate is 2 seconds.      |
| W   | Changes between wide and normal display modes.<br>In wide mode, CPView fits the screen horizontally. |
| S   | Manually sets the number of rows or columns.                                                         |
| M   | Switches on/off the mouse.                                                                           |
| P   | Pauses and resumes the collection of statistics.                                                     |

Use these keys to save statistics, show help, and refresh statistics:

| Key       | Description                                                                                                                                         |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| C         | Saves the current page to a file. The file name format is:<br><code>cpview_&lt;ID of the cpview process&gt;.cap&lt;Number of the capture&gt;</code> |
| H         | Shows a tooltip with CPView options.                                                                                                                |
| Space bar | Immediately refreshes the statistics.                                                                                                               |

# pdp

## Description

These commands control and monitor the *pdpd* process.

## Syntax

```
pdp <command> [<parameter> [<option>]]
```

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (*vsenv <VS ID>*).

## Commands

| Parameter                                      | Description                                                                                                                                                |
|------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| No Parameters                                  | Shows available options for this command and exits.                                                                                                        |
| <i>ad</i> <parameter><br><option>              | For the AD Query, adds (or removes) an identity to the Identity Awareness database on the Security Gateway.<br>See <a href="#">"pdp ad" on page 1842</a> . |
| <i>auth</i> <parameter><br><option>            | Shows authentication or authorization options.<br>See <a href="#">"pdp auth" on page 1844</a> .                                                            |
| <i>broker</i> <parameter><br><option>          | Controls the PDP Identity Broker.<br>See <a href="#">"pdp broker" on page 1848</a> .                                                                       |
| <i>conciliation</i><br><parameter><br><option> | Controls the session conciliation mechanism.<br>See <a href="#">"pdp conciliation" on page 1853</a> .                                                      |
| <i>connections</i><br><parameter>              | Shows the PDP connections with the PEP gateways, Terminal Servers, and Identity Collectors.<br>See <a href="#">"pdp connections" on page 1855</a> .        |
| <i>control</i><br><parameter><br><option>      | Controls the PDP parameters.<br>See <a href="#">"pdp control" on page 1856</a> .                                                                           |

| Parameter                          | Description                                                                                                                |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| debug <parameter><br><option>      | Controls the PDP debug.<br>See <a href="#">"pdp debug" on page 1859</a> .                                                  |
| idc <parameter><br><option>        | Operations related to Identity Collector.<br>See <a href="#">"pdp idc" on page 1862</a> .                                  |
| idp <parameter><br><option>        | Operations related to SAML-based authentication.<br>See <a href="#">"pdp idp" on page 1866</a> .                           |
| monitor<br><parameter><br><option> | Monitors the status of connected PDP sessions.<br>See <a href="#">"pdp monitor" on page 1867</a> .                         |
| muh <parameter><br><option>        | Shows Multi-User Hosts (MUHs).<br>See <a href="#">"pdp muh" on page 1870</a> .                                             |
| nested_groups<br><parameter>       | Shows LDAP Nested groups configuration.<br>See <a href="#">"pdp nested_groups" on page 1871</a> .                          |
| network<br><parameter>             | Shows information about network related features.<br>See <a href="#">"pdp network" on page 1875</a> .                      |
| radius <parameter><br><option>     | Shows and configures the RADIUS accounting options.<br>See <a href="#">"pdp radius" on page 1876</a> .                     |
| roles <parameter><br><option>      | Shows the user role information.<br>See <a href="#">"pdp roles" on page 1879</a> .                                         |
| status <parameter>                 | Shows PDP status information, such as start time or configuration time.<br>See <a href="#">"pdp status" on page 1882</a> . |
| tasks_manager<br><parameter>       | Shows the status of the PDP tasks.<br>See <a href="#">"pdp tasks_manager" on page 1883</a> .                               |
| timers <parameter>                 | Shows PDP timers information for each session.<br>See <a href="#">"pdp timers" on page 1884</a> .                          |
| topology_map                       | Shows topology of all PDP and PEP addresses.<br>See <a href="#">"pdp topology_map" on page 1885</a> .                      |
| tracker<br><parameter>             | Adds the TRACKER topic to the PDP logs.<br>See <a href="#">"pdp tracker" on page 1886</a> .                                |

| Parameter          | Description                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| update <parameter> | Recalculates users and computers group membership.<br>See " <a href="#">pdp update</a> " on page 1887.                                |
| vpn <parameter>    | Shows connected VPN gateways that send identity data from VPN Remote Access Clients.<br>See " <a href="#">pdp vpn</a> " on page 1888. |

# pdp ad

## General Syntax

```
pdp ad
    associate <options>
    disassociate <options>
```

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vsenv <VS ID>`).

## The 'pdp ad associate' command

### Description

For the AD Query, adds an identity to the Identity Awareness database on the Security Gateway.

The group data must be in the AD.

### Syntax

```
pdp ad associate ip <IP Address> u <Username> d <Domain> [m
<Computer Name>] [t <Timeout>] [s]
```

### Parameters

| Parameter                            | Description                                                            |
|--------------------------------------|------------------------------------------------------------------------|
| <code>ip &lt;IP Address&gt;</code>   | Specifies the IP address for the identity.                             |
| <code>u &lt;Username&gt;</code>      | Specifies the username for the identity.                               |
| <code>d &lt;Domain&gt;</code>        | Specifies the Domain of the ID server.                                 |
| <code>m &lt;Computer Name&gt;</code> | Specifies the computer that is defined for the identity.               |
| <code>t &lt;Timeout&gt;</code>       | Specifies the timeout for the AD Query.<br>Default timeout is 5 hours. |

| Parameter | Description                                                                                                                                                   |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| s         | Associates the "u <Username>" and the "m <Computer>" parameters sequentially.<br>First, adds the "<Computer>" and then adds the "<Username>" to the database. |

### The 'pdp ad disassociate' command

#### Description

For the AD Query, removes the identity from the Identity Awareness database on the Security Gateway.

Identity Awareness does not authenticate a user that is removed.

#### Syntax

```
pdp ad disassociate ip <IP Address> {u <Username> | m <Computer Name>} [r {override | probed | timeout}]
```

#### Parameters

| Parameter                       | Description                                                                                 |
|---------------------------------|---------------------------------------------------------------------------------------------|
| ip <IP Address>                 | Specifies the IP address for the identity.                                                  |
| u <Username>                    | Specifies the username for the identity.                                                    |
| m <Computer Name>               | Specifies the computer that is defined for the identity.                                    |
| r {override   probed   timeout} | Specifies the reason to show in SmartConsole on the <b>Logs &amp; Events &gt; Logs</b> tab. |

# pdp auth

## Description

Configures authentication/authorization options for PDP.

## Syntax

```
pdp auth
    allow_empty_result <options>
    count_in_non_ldap_group <options>
    fetch_by_sid <options>
    force_domain <options>
    kerberos_any_domain <options>
    kerberos_encryption <options>
    reauth_agents_after_policy <options>
    recovery_interval <options>
    username_password <options>
```

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vsenv <VS ID>`).

## Parameters

| Parameter                                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>allow_empty_result</code><br><code>&lt;options&gt;</code>      | <p>Shows the current configuration of fetching of local groups from the AD server based on SID.</p> <p>Configures that the fetching of local groups from the AD server based on SID should succeed, even if all SIDs are foreign.</p> <p>The available <code>&lt;options&gt;</code> are:</p> <ul style="list-style-type: none"> <li>Disable the fetching of local groups:<br/> <pre>pdp auth allow_empty_result disable</pre> </li> <li>Enable the fetching of local groups:<br/> <pre>pdp auth allow_empty_result enable</pre> </li> <li>Show the current configuration:<br/> <pre>pdp auth allow_empty_result status</pre> </li> </ul> |
| <code>count_in_non_ldap_group</code><br><code>&lt;options&gt;</code> | <p>Shows and configures the identification of membership to individual users that are selected in the user picker and LDAP branch groups in SmartConsole.</p> <p>The available <code>&lt;options&gt;</code> are:</p> <ul style="list-style-type: none"> <li>Disable the identification of membership:<br/> <pre>pdp auth count_in_non_ldap_group disable</pre> </li> <li>Enable the identification of membership:<br/> <pre>pdp auth count_in_non_ldap_group enable</pre> </li> <li>Show the current configuration:<br/> <pre>pdp auth count_in_non_ldap_group status</pre> </li> </ul>                                                  |
| <code>fetch_by_sid</code><br><code>&lt;options&gt;</code>            | <p>Shows and configures the fetching of local groups from the AD server based on SID.</p> <p>The available <code>&lt;options&gt;</code> are:</p> <ul style="list-style-type: none"> <li>Disable the fetching of local groups:<br/> <pre>pdp auth fetch_by_sid disable</pre> </li> <li>Enable the fetching of local groups:<br/> <pre>pdp auth fetch_by_sid enable</pre> </li> <li>Show the current configuration:<br/> <pre>pdp auth fetch_by_sid status</pre> </li> </ul>                                                                                                                                                               |

| Parameter                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

# pdp broker

## Description

These commands control the PDP Identity Broker.

## Syntax

```
pdp broker
    debug {set | unset} <options>
    discard <options>
    identity_cache_mode status
    reconnect <options>
    session <options>
    status [-e]
    sync <options>
```

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vsenv <VS ID>`).

## Parameters

| Parameter                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                    |

# pdp conciliation

## Description

Controls the session conciliation mechanism.

## Syntax

```
pdp conciliation
    adq_single_user <option>
    api_multiple_users <option>
    idc_multiple_users <option>
    rad_multiple_users <option>
```

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vsenv <VS ID>`).

## Parameters

| Parameter                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>adq_single_user &lt;option&gt;</code> | <p>Shows and controls the assumption that single AD Query user is connected on each computer.</p> <p>The available <i>&lt;options&gt;</i> are:</p> <ul style="list-style-type: none"> <li>■ Disable this behavior: <div>pdp conciliation adq_single_user disable</div> </li> <li>■ Enable this behavior: <div>pdp conciliation adq_single_user enable</div> </li> <li>■ Show the current status (enabled or disabled): <div>pdp conciliation adq_single_user stat</div> </li> </ul> |

| Parameter                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| api_multiple_users <option> | <p>Shows and controls the assumption that multiple Web-API users are connected on each computer.</p> <p>The available &lt;options&gt; are:</p> <ul style="list-style-type: none"> <li>Disable this behavior: <pre>pdp conciliation api_multiple_users disable</pre> </li> <li>Enable this behavior: <pre>pdp conciliation api_multiple_users enable</pre> </li> <li>Show the current status (enabled or disabled): <pre>pdp conciliation api_multiple_users stat</pre> </li> </ul>            |
| idc_multiple_users <option> | <p>Shows and controls the assumption that multiple Identity Collector users are connected on each computer.</p> <p>The available &lt;options&gt; are:</p> <ul style="list-style-type: none"> <li>Disable this behavior: <pre>pdp conciliation idc_multiple_users disable</pre> </li> <li>Enable this behavior: <pre>pdp conciliation idc_multiple_users enable</pre> </li> <li>Show the current status (enabled or disabled): <pre>pdp conciliation idc_multiple_users stat</pre> </li> </ul> |

# pdp connections

## Description

Shows the PDP connections with PEP gateways, Terminal Servers, and Identity Collectors.

## Syntax

```
pdp connections
    idc
    pep
    ts
```

### Important:

- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vse nv <VS ID>`).

## Parameters

| Parameter        | Description                                                                       |
|------------------|-----------------------------------------------------------------------------------|
| <code>idc</code> | Shows a list of connected Identity Collectors.                                    |
| <code>pep</code> | Shows the connection status of all the PEPs, which the current PDP should update. |
| <code>ts</code>  | Shows a list of all connected Terminal Servers.                                   |

# pdp control

## Description

Provides commands to control the PDP.

## Syntax

```
pdp control
    intelli_sync
    log_enrichmant {enable | disable}
    multi_instance
        hash_function {set <Hash> | status}
        set <Number>
        status
    nac_client_grace_period [<Number>]
    portal_dual_stack {enable | disable}
    revoke_ip <IP address>
    revoke_pt_key <Session ID>
    scaled_sharing
        affine_redis_CPU {<CPU Core ID> | none}
        affine_redis_inval_CPU <CPU Core ID> | none}
        ida_go_portal debug
            set <Level> <Configuration File> {true | false}
            status
        show_configurations
        show_pep_configurations <Name of PEP>
        status
    sync
```

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vsenv <VS ID>`).

## Parameters

| Parameter                                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>intelli_sync</code>                                         | Synchronizes all data to the local intelligence.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>log_enrichmant</code><br><code>{enable   disable}</code>    | Enables and disables additional log fields ( <code>function</code> , <code>manufacturer</code> , <code>model</code> , <code>id</code> ).<br>Default: disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

# pdp debug

## Description

Controls the debug of the PDP.

## Syntax

```
pdp debug
  async1
  ccc {off | on}
  memory
  off
  on
  reset
  rotate
  set <Topic Name> <Severity>
  spaces [<0 - 5>]
  stat
  unset <Topic Name>
```

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vsenv <VS ID>`).

## Parameters

| Parameter                   | Description                                                                                                                                                                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>async1</code>         | Tests the <code>async</code> command line with the <code>echo</code> command for 30 seconds.                                                                                                                                                                             |
| <code>ccc {off   on}</code> | Configures whether to write the CCC debug logs into the PDP log file - <code>\$FWDIR/log/pdpd.elg</code> <ul style="list-style-type: none"> <li>■ <code>on</code> - Writes the CCC debug logs</li> <li>■ <code>off</code> - Does not write the CCC debug logs</li> </ul> |
| <code>memory</code>         | Shows the memory consumption by the <code>pdpd</code> daemon.                                                                                                                                                                                                            |
| <code>off</code>            | Disables the PDP debug.                                                                                                                                                                                                                                                  |

| Parameter                             | Description                                                                                                                                                                                                                                                                                |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>spaces [&lt;0 - 5&gt;]</code>   | Shows and configures the number of indentation spaces in the <code>\$FWDIR/log/pdpc.elg</code> file.<br>You can specify the number of spaces: <ul style="list-style-type: none"> <li>▪ 0 (this is the default)</li> <li>▪ 1</li> <li>▪ 2</li> <li>▪ 3</li> <li>▪ 4</li> <li>▪ 5</li> </ul> |
| <code>stat</code>                     | Shows the PDP current debug status.                                                                                                                                                                                                                                                        |
| <code>unset &lt;Topic Name&gt;</code> | Unsets the specified Debug Topic(s).                                                                                                                                                                                                                                                       |

 **Important** - When you enable the debug, it affects the performance of the *pdpc* daemon. Make sure to disable the debug after you complete your troubleshooting.

# pdp idc

## Description

Operations related to Identity Collector.

## Syntax

```
pdp idc
  groups_consolidation <options>
  groups_update <options>
  muh <options>
  service_accounts <options>
  status
```

 **Important:**

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vsenv <VS ID>`).

## Parameters

| Parameter                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| status    | Shows the status of configured identity sources (Identity Collectors).                                                                                                                                                                                                                                                                                                              |

# pdp idp

## Description

Operations related to SAML-based authentication.

## Syntax

```
pdp idp groups <options>
```

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vsenv <VS ID>`).

## Parameters

| Parameter                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

# pdp monitor

## Description

Monitors the status of connected PDP sessions.

You can run different queries with the commands below to get the output, in which you are interested.

## Syntax

```
pdp monitor
  all
  client_type <Client Type>
  cv_ge <Version>
  cv_le <Version>
  groups <Group Name>
  ip <IP address>
  machine <Computer Name>
  machine_exact
  mad
  network
  s_port
  summary
  user <Username>
  user_exact
```

### Important:

- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vsenv <VS ID>`).

## Parameters

| Parameter | Description                                   |
|-----------|-----------------------------------------------|
| all       | Shows information for all connected sessions. |

| Parameter                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| client_type<br><Client Type> | Shows all sessions that connect through the specified client type.<br>Possible client types are: <ul style="list-style-type: none"> <li>▪ "AD Query" - User was identified by the AD Query.</li> <li>▪ "Identity Agent" - User or computer was identified by an Identity Awareness Agent.</li> <li>▪ portal - User was identified by the Captive Portal.</li> <li>▪ unknown - User was identified by an unknown source.</li> </ul> |
| cv_ge<br><Version>           | Shows all sessions that are connected with a client version that is higher than (or equal to) the specified version.                                                                                                                                                                                                                                                                                                               |
| cv_le<br><Version>           | Shows all sessions that are connected through a client version that is lower than (or equal to) the specified version.                                                                                                                                                                                                                                                                                                             |
| groups <Group Name>          | Shows all sessions of users or computers that are members of the specified group.                                                                                                                                                                                                                                                                                                                                                  |
| ip <IP address>              | Shows session information for the specified IP address.                                                                                                                                                                                                                                                                                                                                                                            |
| machine<br><Computer Name>   | Shows session information for the specified computer name.                                                                                                                                                                                                                                                                                                                                                                         |
| machine_exact                | Shows sessions filtered by the exact computer name.                                                                                                                                                                                                                                                                                                                                                                                |
| mad                          | Shows all sessions that relate to a managed asset.<br>For example, all sessions that successfully performed computer authentication.                                                                                                                                                                                                                                                                                               |
| network                      | Shows sessions filtered by a network wildcard.<br>For example: 192.168.72.*                                                                                                                                                                                                                                                                                                                                                        |
| s_port                       | Shows sessions filtered by the assigned source port (MUH sessions only).                                                                                                                                                                                                                                                                                                                                                           |
| summary                      | Shows the summary monitoring data.                                                                                                                                                                                                                                                                                                                                                                                                 |
| user<br><Username>           | Shows session information for the specified user name.                                                                                                                                                                                                                                                                                                                                                                             |
| user_exact                   | Shows sessions filtered by the exact user.                                                                                                                                                                                                                                                                                                                                                                                         |

**Example - Show the connected user behind the IP address 192.0.2.1**

```
pdp monitor ip 192.0.2.1
```

 **Note** - The last field "Published" indicates whether the session information was already published to the Gateway PEPs, whose IP addresses are listed.

# pdp muh

## Description

Shows Multi-User Hosts (MUHs).

## Syntax

```
pdp muh status
```

### Important:

- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vse nv <VS ID>`).

# pdp nested\_groups

## Description

Configures the Security Gateway queries LDAP Nested Groups.

Shows the current configuration LDAP Nested Group queries.

## Syntax

```
pdp nested_groups
    auto_tune {enable | disable}
    clear
    depth <options>
    disable
    enable
    show
    status
    __set_state <options>
```

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vse nv <VS ID>`).

## Parameters

| Parameter                                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>auto_tune</code><br><code>{enable   disable}</code> | <p>Enables and disables the auto-tune feature.</p> <p>This feature calculates and automatically selects the state of Nested Groups based on the LDAP configuration on the Security Gateway and the Management Server.</p> <p> <b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ When you enable this feature, the Security Gateway automatically configures the best the state of Nested Groups it calculated.</li> <li>▪ When you disable this feature, the Security Gateway automatically returns to the state of Nested Groups you configured earlier with the "<code>__set_state</code>" parameter.</li> </ul> <p> <b>Best Practice</b> - Enable this feature on the Policy Decision Point (PDP) to increase the performance.</p> |
| <code>clear</code>                                        | Clears the list of users, for which the depth was not enough.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>depth &lt;1 - 40&gt;</code>                         | Configures the nested groups depth (between 1 and 40).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>disable</code>                                      | Disables the nested groups.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>enable</code>                                       | Enables the nested groups.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>show</code>                                         | Shows a list of users, for which the depth was not enough.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>status</code>                                       | Shows the configuration status of nested groups.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

# pdp network

## Description

Shows information about network related features.

## Syntax

```
pdp network {info | registered}
```

### Important:

- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vse nv <VS ID>`).

## Parameters

| Parameter  | Description                                                                     |
|------------|---------------------------------------------------------------------------------|
| info       | Shows a list of networks known by the PDP.                                      |
| registered | Shows the mapping of a network address to the registered gateways (PEP module). |

# pdp radius

## Description

Shows and configures the RADIUS accounting options.

## Syntax

```
pdp radius
  ip
    reset
    set <options>
  groups
    fetch <options>
    reset
    set <options>
  parser
    reset
    set <options>
  roles
    fetch <options>
    reset
    set <options>
  status
```

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vse nv <VS ID>`).

## Parameters

| Parameter                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

# pdp roles

## General Syntax

```
pdp roles
    extract
    fetch <options>
```

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vsenv <VS ID>`).

## The 'pdp roles extract' command

### Description

Extracts and shows the roles from the file `$FWDIR/tmp/roles_command_output.txt` that was created with the "pdp roles fetch" command.

### Syntax

```
pdp roles extract
```

## The 'pdp roles fetch' command

### Description

Fetches the roles that match the provided Access Role information and saves the output in the `$FWDIR/tmp/roles_command_output.txt` file.

### Syntax

```
pdp roles fetch [-ip <IP Address>]
    -u "<Username>" -is "<Identity Source>"
    -ug "<User Group 1>","<User Group 2>","..."
    -mg "<Machine Group 1>","<Machine Group 2>","..."
```

Parameters

| Parameter                                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-ip &lt;IP Address&gt;</code>                                  | <p><b>Optional.</b></p> <p>Specifies the IP address of identity, host, or session to calculate and fetch Access Roles that also contain explicitly selected objects in the <b>Networks</b> pane.</p> <p>Example for an Access Role object, in which a Host object with the IPv4 address 5.5.5.5 was selected in the <b>Networks</b> pane:</p> <pre>pdp roles fetch -i 5.5.5.5 -u "user_1" -is "AD_Query"</pre>                                                                                                                                                                                                                                                                                                                                                |
| <code>-u "&lt;Username&gt;" -is "&lt;Identity Source&gt;"</code>     | <p>Specifies the username and the identity source.</p> <p>The available identity sources are (case-sensitive):</p> <ul style="list-style-type: none"><li>portal</li><li>Identity_Agent</li><li>Remote_Access</li><li>AD_Query</li><li>IFMAP</li><li>Terminal_Server_Identity_Agent</li><li>Radius_Accounting</li></ul> <p> <b>Important</b> - If in the Access Role object you explicitly selected objects in the <b>Networks</b> and <b>Users</b> panes, you must also use the parameter <code>-ip &lt;IP Address&gt;</code>.</p> <p>Examples:</p> <pre>pdp roles fetch -u "user_1" -is "AD_Query"</pre> <pre>pdp roles fetch -i 5.5.5.5 -u "user_1" -is "AD_Query"</pre> |

# pdp status

## Description

Shows PDP status information, such as start time or configuration time.

## Syntax

```
pdp status show
```

 **Important:**

- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vseenv <VS ID>`).

## Parameters

| Parameter | Description            |
|-----------|------------------------|
| show      | Shows PDP information. |

# pdp tasks\_manager

## Description

Shows the status of the PDP tasks (current running, previous, and pending tasks).

## Syntax

```
pdp tasks_manager status
```

### Important:

- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vsenv <VS ID>`).

## Parameters

| Parameter | Description                        |
|-----------|------------------------------------|
| status    | Shows the status of the PDP tasks. |

# pdp timers

## Description

Shows PDP timers information for each PDP session.

## Syntax

```
pdp timers show
```

### Important:

- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vse nv <VS ID>`).

## Parameters

| Parameter | Description                                                                                                                                                                                                                                                         |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| show      | <p>Shows PDP timers information for each PDP session:</p> <ul style="list-style-type: none"><li>■ User Auth Timer</li><li>■ Machine Auth Timer</li><li>■ Pep Cache Timer</li><li>■ Compliance Timer</li><li>■ Keep Alive Timer</li><li>■ Ldap Fetch Timer</li></ul> |

# pdp topology\_map

## Description

Shows topology of all PDP and PEP addresses.

## Syntax

```
pdp topology_map
```

### Important:

- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vse nv <VS ID>`).

# pdp tracker

## Description

During the PDP debug, adds the `TRACKER` debug topic to the PDP logs (this is enabled by default).

This is very useful when you monitor the PDP-to-PEP identity sharing and other communication in distributed environments.

You can set this manually if you add the `TRACKER` topic to the PDP debug.

## Syntax

```
pdp tracker {off | on}
```

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vsenv <VS ID>`).

## Parameters

| Parameter        | Description                                                         |
|------------------|---------------------------------------------------------------------|
| <code>off</code> | Disables the logging of <code>TRACKER</code> events in the PDP log. |
| <code>on</code>  | Enables the logging of <code>TRACKER</code> events in the PDP log.  |

# pdp update

## Description

Initiates a recalculation of group membership for all users and computers.

**Important** - This command does **not** update deleted accounts.

## Syntax

```
pdp update {all | specific}
```

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vsenv <VS ID>`).

## Parameters

| Parameter | Description                                                       |
|-----------|-------------------------------------------------------------------|
| all       | Recalculates group membership for all users and computers.        |
| specific  | Recalculates group membership for a specified user or a computer. |

# pdp vpn

## Description

Shows the connected VPN Gateways that send identity data for VPN Remote Access Client.

## Syntax

```
pdp vpn show
```

### Important:

- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vsenv <VS ID>`).

## Parameters

| Parameter | Description                       |
|-----------|-----------------------------------|
| show      | Shows the connected VPN gateways. |

# pep

## Description

Provides commands to control and monitor the *PEPD* process (see below for options).

## Syntax

```
pep <command> [<parameter> [<option>]]
```

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vsenv <VS ID>`).

## Commands

| Command                                               | Description                                                                                                                          |
|-------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <code>control &lt;parameter&gt; &lt;option&gt;</code> | Controls the PEP parameters.<br>See <a href="#">"pep control" on page 1890</a> .                                                     |
| <code>debug &lt;parameter&gt; &lt;option&gt;</code>   | Controls the PEP debug.<br>See <a href="#">"pep debug" on page 1893</a> .                                                            |
| <code>show &lt;parameter&gt; &lt;option&gt;</code>    | Shows PEP information.<br>See <a href="#">"pep show" on page 1895</a> .                                                              |
| <code>tracker &lt;parameter&gt;</code>                | During the PEP debug, adds the <code>TRACKER</code> debug topic to the PEP logs.<br>See <a href="#">"pep tracker" on page 1898</a> . |

# pep control

## Description

Provides commands to control the PEP.

## Syntax

```
pep control
    extended_info_storage <options>
    gbuf_cache <option>
    identity_cache_mode status
    kbuf_cache <option>
    portal_dual_stack <options>
    tasks_manager status <options>
```

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vsenv <VS ID>`).

## Parameters

| Parameter                                          | Description                                                                                                                                                                                                                                                                                                    |
|----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>extended_info_storage &lt;options&gt;</code> | <p>Controls whether PEP stores the extended identities information for debug.</p> <p>The available <i>&lt;options&gt;</i> are:</p> <ul style="list-style-type: none"> <li>■ <code>disable</code> - PEP does not store the information.</li> <li>■ <code>enable</code> - PEP stores the information.</li> </ul> |

| Parameter                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

# pep debug

## Description

Controls the debug of the PEP.

## Syntax

```

pep debug
    memory
    off
    on
    reset
    rotate
    set <options>
    spaces [<options>]
    stat
    unset <options>
  
```

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vsenv <VS ID>`).

## Parameters

| Parameter | Description                                                                                                                                                                                           |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| memory    | Displays the memory consumption by the <i>pepd</i> daemon.                                                                                                                                            |
| off       | Disables the PEP debug.                                                                                                                                                                               |
| on        | Enables the PEP debug.<br><b>Important</b> - After you run this command "pep debug on", you must run the command "pep debug set ..." to determine the required filter.                                |
| reset     | Resets the PEP debug options for Debug Topics and Severities.<br><b>Important</b> - After you run this command "pep debug reset ...", you must run the command "pep debug off" to turn off the debug. |

| Parameter                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| stat                                 | Shows the PEP current debug status.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| unset <Topic Name>                   | Unsets the specified Debug Topic(s).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

 **Important** - When you enable the debug, it affects the performance of the *pepd* daemon. Make sure to turn off the debug after you complete your troubleshooting.

# pep show

## Description

Shows information about PEP.

## Syntax

```

pep show
  conciliation_clashes
    all
    clear
    ip <Session IP Address>
  network
    pdp
    registration
  pdp
    all
    id <ID of PDP>
  stat
  topology_map
  user
    all
    query
      cid <IP[,ID]>
      cmp <Compliance>
      mchn <Computer Name>
      mgrp <Group>
      pdp <IP[,ID]>
      role <Identity Role>
      ugrp <Group>
      uid <UID String>
      usr <Username>

```

### Important:

- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vsenv <VS ID>`).

## Parameters

| Parameter                          | Description                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| conciliation_<br>clashes <options> | Shows session conciliation clashes.<br>The available <options> are: <ul style="list-style-type: none"> <li>all - Show all conciliation clashes.</li> <li>clear - Clears all session clashes.</li> <li>ip &lt;Session IP Address&gt; - Show all conciliation clashes filtered by the specified session IP address.</li> </ul>                                                             |
| network <options>                  | Shows network related information.<br>The available <options> are: <ul style="list-style-type: none"> <li>pdp - Shows the Network-to-PDP mapping table.</li> <li>registration - Shows the networks registration table.</li> </ul>                                                                                                                                                        |
| pdp <options>                      | Shows the communication channel between the PEP and the PDP.<br>Available <options> are: <ul style="list-style-type: none"> <li>all - Shows all connected PDPs.</li> <li>id - Shows the information for the specified PDP.</li> </ul>                                                                                                                                                    |
| stat                               | Shows the last time the <i>pepd</i> daemon was started and the last time a policy was received.<br> <b>Important</b> - Each time the <i>pepd</i> daemon starts, it loads the policy and the two timers. The times between the <i>pepd</i> daemon start and when it fetched the policy are very close. |
| topology_map                       | Shows topology of all PDP and PEP addresses.                                                                                                                                                                                                                                                                                                                                             |

| Parameter                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>user &lt;options&gt;</code> | <p>Shows the status of sessions that PEP knows.<br/>         You can perform various queries to get the applicable output (see below).<br/>         The available <i>&lt;options&gt;</i> are:</p> <ul style="list-style-type: none"> <li>▪ <code>all</code> - Shows the list of all clients.</li> <li>▪ <code>query</code> - Queries the list of users based on the specified filters:             <ul style="list-style-type: none"> <li>• <code>cid &lt;IP[, ID]&gt;</code> - Matches entries of clients with the specified Client ID.</li> <li>• <code>cmp &lt;Compliance&gt;</code> - Matches entries with the specified compliance.</li> <li>• <code>mchn &lt;Computer Name&gt;</code> - Matches entries with the specified computer name.</li> <li>• <code>mgrp &lt;Group&gt;</code> - Matches entries with the specified machine group.</li> <li>• <code>pdp &lt;IP[, ID]&gt;</code> - Matches entries, which the specified PDP updated.</li> <li>• <code>role &lt;Identity Role&gt;</code> - Matches entries with the specified identity role.</li> <li>• <code>ugrp &lt;Group&gt;</code> - Matches entries with the specified user group.</li> <li>• <code>uid &lt;UID String&gt;</code> - Matches entries with the specified full or partial UID.</li> <li>• <code>usr &lt;Username&gt;</code> - Matches entries with the specified username.</li> </ul> </li> </ul> <p> <b>Note</b> - You can use multiple query filters at the same time to create a logical <i>AND</i> correlation between them.<br/>         For example, to show all users that have a sub-string of "jo" AND are part of the user group "Employees" you can use this query syntax:</p> <pre># pep show user query usr jo ugrp Employees</pre> |

# pep tracker

## Description

During the PEP debug, adds the `TRACKER` debug topic to the PEP logs (this is enabled by default).

This is very useful when you monitor the PDP-to-PEP identity sharing and other communication in distributed environments.

You can set this manually if you add the `TRACKER` topic to the PEP debug.

## Syntax

```
pep tracker {off | on}
```

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vsenv <VS ID>`).

## Parameters

| Parameter        | Description                                                         |
|------------------|---------------------------------------------------------------------|
| <code>off</code> | Disables the logging of <code>TRACKER</code> events in the PEP log. |
| <code>on</code>  | Enables the logging of <code>TRACKER</code> events in the PEP log.  |

# test\_ad\_connectivity

## Description

This utility runs connectivity tests from the Security Gateway to an AD domain controller.

You can define the parameters for this utility in one of these ways:

- In the command line as specified below
- In the `$FWDIR/conf/test_ad_connectivity.conf` configuration file.

Parameters you define in the `$FWDIR/conf/test_ad_connectivity.conf` file cannot contain white spaces and cannot be within quotation marks.

 **Important:**

- Parameters you enter in the command line override the parameters you enter in the configuration file.
- This utility saves its output in the file you specify with the "-o" parameter.  
In addition, examine the `$FWDIR/log/test_ad_connectivity.elg` file.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- In the VSNext / Legacy VSX mode, you must run the applicable commands in to the context of the applicable Virtual Gateway / Legacy Virtual System (`vsenv <VS ID>`).

## Syntax

```
[Expert@HostName:0]# $FWDIR/bin/test_ad_connectivity -h

[Expert@HostName:0]# $FWDIR/bin/test_ad_connectivity <Parameter_1
Value_1> <Parameter Value_2> ... <Parameter_N Value_N>
...<Parameters And Options>
```

 **Important** - On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

## Parameters

| Parameter | Mandatory / Optional | Description              |
|-----------|----------------------|--------------------------|
| -h        | Optional             | Shows the built-in help. |

| Parameter                     | Mandatory / Optional                                                                                                                 | Description                                                                                                     |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------|
| -a                            | <b>Mandatory</b><br>Use only one of these options:<br><ul style="list-style-type: none"><li>■ -a</li><li>■ -c</li><li>■ -p</li></ul> | Prompts the user for the password on the screen.                                                                |
| -b <LDAP Search Base String>  | Optional                                                                                                                             | Specifies the LDAP Search Base String.                                                                          |
| -c <Password in Clear Text>   | <b>Mandatory</b><br>Use only one of these options:<br><ul style="list-style-type: none"><li>■ -a</li><li>■ -c</li><li>■ -p</li></ul> | Specifies the user's password in clear text.                                                                    |
| -d <Domain Name>              | <b>Mandatory</b>                                                                                                                     | Specifies the domain name of the AD (for example, ad.mycompany.com).                                            |
| -D <User DN>                  | <b>Mandatory</b>                                                                                                                     | Overrides the LDAP user DN (the utility does not try to figure out the DN automatically).                       |
| -f <AD Fingerprint for LDAPS> | Optional                                                                                                                             | Specifies the AD fingerprint for LDAPS.                                                                         |
| -i <IPv4 address of DC>       | <b>Mandatory</b>                                                                                                                     | Specifies the IPv4 address of the AD domain controller to tested.                                               |
| -I <IPv6 address of DC>       | <b>Mandatory</b>                                                                                                                     | Specifies the IPv6 address of the AD domain controller to test.                                                 |
| -o <File Name>                | <b>Mandatory</b>                                                                                                                     | Specifies the name of the output file. This utility always saves the output file in the \$FWDIR/tmp/ directory. |

| Parameter                   | Mandatory / Optional                                                                                                                 | Description                                                                                                                                                                            |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -p<br><Obfuscated Password> | <b>Mandatory</b><br>Use only one of these options:<br><ul style="list-style-type: none"><li>■ -a</li><li>■ -c</li><li>■ -p</li></ul> | Specifies the user's password in obfuscated text.                                                                                                                                      |
| -l                          | Optional                                                                                                                             | Runs LDAP connectivity test only (no WMI test).                                                                                                                                        |
| -L <Timeout>                | Optional                                                                                                                             | Specifies the timeout (in milliseconds) for the LDAP test only.<br>If this timeout expires, and the LDAP test still runs, then both LDAP connectivity and WMI connectivity tests fail. |
| -M                          | Optional                                                                                                                             | Run the utility in demo mode.                                                                                                                                                          |
| -r <Port Number>            | Optional                                                                                                                             | Specifies the LDAP or LDAPS connection port number.<br>The default ports are:<br><ul style="list-style-type: none"><li>■ LDAP - 389</li><li>■ LDAPS - 636</li></ul>                    |
| -s                          | Optional                                                                                                                             | Specifies that LDAP connection must be over SSL.                                                                                                                                       |
| -t <Timeout>                | Optional                                                                                                                             | Specifies the total timeout (in milliseconds) for both LDAP connectivity and WMI connectivity tests.                                                                                   |
| -u <Username>               | <b>Mandatory</b>                                                                                                                     | Specifies the administrator user name on the AD.                                                                                                                                       |
| -v                          | Optional                                                                                                                             | Prints the full path to the specified output file.                                                                                                                                     |
| -x <Domain Name>            | <b>Mandatory</b>                                                                                                                     | Specifies the domain name of the AD (for example, ad.mycompany.com).<br>Utility prompts the user for the password.                                                                     |
| -w                          | Optional                                                                                                                             | Runs WMI connectivity test only (no LDAP test).                                                                                                                                        |

Example

|               |                                                                                                                                                                                                                                                          |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IPv4 of AD DC | 192.168.230.240                                                                                                                                                                                                                                          |

| Syntax        | <pre>[Expert@GW:0]# \$FWDIR/bin/test_ad_connectivity -u "Administrator" -c "aaaa" -D "CN=Administrator,CN=Users,DC=mydc,DC=local" -d mydc.local -i 192.168.230.240 -b "DC=mydc,DC=local" -o test.txt [Expert@GW:0]#</pre>                                |
| Output        | <pre>[Expert@GW:0]# cat \$FWDIR/tmp/test.txt (     :status (SUCCESS_LDAP_WMI)     :err_msg ("WMI_SUCCESS;LDAP_SUCCESS")     :ldap_status (LDAP_SUCCESS)     :wmi_status (WMI_SUCCESS)     :timestamp ("Mon Feb 26 10:17:41 2018") ) [Expert@GW:0]#</pre> |

 **Note** - In order to know the output is authentic, pay attention that the timestamp is the same as the local time.

# VPN Commands

VPN commands generate status information regarding VPN processes, or are used to stop and start specific VPN services.

All VPN commands are executed on the Security Gateway and Cluster Members.

For more information about VPN, see the:

- [\*R82.10 Site to Site VPN Administration Guide\*](#).
- [\*R82.10 Remote Access VPN Administration Guide\*](#).

# ike debug

## Background

Starting in R81.10, separate daemons handle different VPN connections.

Starting in R81.20, these are the responsibilities of the different daemons - `vpnd`, `iked`, and `cccd`:

### The VPN daemon "`vpnd`"

Handles these VPN connections:

- All connections from non-IKE Remote Access clients (SSL Network Extender, Capsule VPN)
- Multi-Portal traffic (SSL / TLS) to a Security Gateway

The VPN daemon on a Security Gateway listens on these ports:

- Tunnel Test: 18234 (UDP)
- L2TP: 1701 (UDP)
- Check Point RDP: 259 (UDP)
- Session infrastructure manager: 9996 (TCP)

The "`vpnd`" daemon is a child of the FWD daemon (see the `$FWDIR/conf/fwauthd.conf` file on a Security Gateway).

### The IKE daemon "`iked`"

Introduced in the R81.10 version.

Handles these VPN connections:

- All connections from IKE Remote Access clients (for example, Endpoint clients)
- All IKE Site-to-Site connections from peer Security Gateways
- Large Scale VPN (LSV) connections
- Connections from SmartLSM ROBO gateways

Listens on these ports on a Security Gateway:

- IKE: 30500 - 30563 (UDP)
- IKE NAT-T: 34500 - 34563 (UDP)
- Tunnel Test: 48234 - 48297 (UDP)
- Check Point RDP: 30259 - 30322 (UDP)
- L2TP: 31701 - 31764 (UDP)

CLI Syntax to control the IKE daemon "`iked`":

```
vpniked {status | enable | disable | calc <Peer IP address>}
```

Starting in R81.20, there can be a maximum of 64 instances of the "iked" daemon that are calculated based on this formula:

```
Number of IKED instances = (Number of CoreXL Firewall Instances)
/ (Value of Kernel Parameter 'ike_num_instances_per_daemon')
```

**Note** - You can configure different values for the kernel parameter 'ike\_num\_instances\_per\_daemon'.

## The CCC daemon "cccd"

Introduced in the R81.10 version.

Responsible for the Client Communication Channel (CCC) protocol, while:

- IKE for the same clients runs in the IKE daemon "iked"
- The TLS layer of the CCC protocol for the same clients runs in the VPN daemon "vpnd"

CLI Syntax to control the CCC daemon "cccd":

```
vpncccd {status | enable | disable}
```

The "cccd" daemon is a child of the FWD daemon (see the `$FWDIR/conf/fwauthd.conf` file on a Security Gateway).

## Enabling and Disabling the IKE daemon "iked"

By default, the IKE daemon "iked" is enabled on the Security Gateway.

If you disable the IKE daemon "iked", then in such a legacy mode the VPN daemon "vpnd" handles all VPN connections.

### Procedure to enable the IKE daemon "iked"

| Step | Instructions                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Enabling and Disabling the CCC Daemon "cccd"

By default, the CCC daemon "cccd" is disabled on the Security Gateway.

In such a legacy mode, the VPN daemon `vpnd` handles all VPN connections.

If you enable the CCC daemon "cccd", then this dedicated daemon handles the Client Communication Channel protocol.

### Procedure to enable the CCC daemon "cccd"

| Step | Instructions                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Description

The "ike debug" command instructs the IKE daemon "iked" to write debug messages to these log files:

| File Description       | Log File for each IKED instance                                                                         |
|------------------------|---------------------------------------------------------------------------------------------------------|
| Main debug output file | \$FWDIR/log/iked0.elg<br>\$FWDIR/log/iked1.elg<br>... ..<br>\$FWDIR/log/iked64.elg                      |
| IKEv1 output           | \$FWDIR/log/iked0.ikev1trace<br>\$FWDIR/log/iked1.ikev1trace<br>... ..<br>\$FWDIR/log/iked64.ikev1trace |
| IKEv2 output           | \$FWDIR/log/iked0.ikev2trace<br>\$FWDIR/log/iked1.ikev2trace<br>... ..<br>\$FWDIR/log/iked64.ikev2trace |

Debugging of the IKE daemon "iked" is based on Debug Topics and Debug Levels:

- A Debug Topic is a specific area, on which to perform debugging.  
Check Point Support provides the specific Debug Topics when needed.
- Debug Levels range from 1 (least informative) to 5 (most informative - write all debug messages).

In addition, see ["vpn debug" on page 1924](#).

## How to see the index number of an IKE daemon "iked" that handles a VPN connection

1. Connect to the command line on the Security Gateway / each Cluster Member / Security Group.
2. Log in to the Expert mode.
3. Get the list of all VPN tunnels (see ["vpn tu tlist" on page 1954](#)):

```
vpn tu tlist -z
```

4. Examine these items in the output:
  - a. In the top section, examine the row "MSPI:".
 

The number that appears after "d:" is the number of the IKE daemon "iked" instance.
  - b. In the bottom section, the "Tunnel Mapping" summary shows the IKE daemon "iked" instance that handles this VPN tunnel.

## Syntax

- ★ **Best Practice** - Use the command `vpn debug trunc ALL=5` that also enables the debug of the IKE daemon "iked" and of the CCC daemon "cccd". See [sk180488](#).

```
ike debug
  on [<Debug_Topic>=<Debug_Level>]
  off
  ikeon [-s <Size_in_MB>]
  ikeoff
  [-i <IKED Index>] trunc [<Debug_Topic>=<Debug_Level>]
  truncon [<Debug_Topic>=<Debug_Level>]
  truncoff
  timeon [<Seconds>]
  timeoff
  ikefail [-s <Size_in_MB>]
  mon
  moff
  say ["String"]
  tunnel [<Level>]
```

## Parameters

| Parameter     | Description               |

### Return Values

- 0 (zero) for success
- any other value for failure (typically, -1 or 1)

# probemon

## Description

On Security Gateways R82 and higher, shows the status of Site to Site VPN Tunnels based on the configured Network Probes (see [sk181994](#)).

This command controls the Probe Monitor daemon (`probemond`) on the Security Gateway.

### Notes:

- You must run this command in the Expert mode.  
On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.
- The "probemon" command does not support IPv6 tunnels.
- The "probemon" command is limited to a maximum of 500 Network Probes.
- In ClusterXL, the Standby Cluster Members may report the status "DOWN" when they use spoofed ICMP probes.
- The "probemond" daemon listens to RPC requests on port 9877 from either the "probemon" CLI or its consumers  
It is possible to configure a different port number in the `$FWDIR/conf/probemond.C` file (required the restart of the daemon).
- The "probemond" daemon uses these probing methods (based on the configuration in the Network Probe):
  - HTTP / HTTPS:  
The Security Gateway sends HTTP / HTTPS requests to the URL configured in the Network Probe.  
The Security Gateway sends these HTTP / HTTPS requests based on standard routing and DNS lookup configuration.
  - ICMP:
    - Direct ICMP:  
The Security Gateway sends ICMP 'Echo Request' packets to the destination IP address / object configured in the Network Probe.  
The Security Gateway sends these ICMP requests based on the standard routing flow.
    - Spoofed ICMP:  
The Security Gateway injects ICMP packets as if they arrive at one of the Security Gateway's interfaces.  
In case of the ICMP probing, the `probemond` daemon automatically determines the ICMP method (Direct ICMP or Spoofed ICMP).
- The "probemond" daemon saves its events in the `$FWDIR/log/probemon.elg*` files.

## Syntax

```
probemon [-d]  
    help  
    start  
    status  
    stop  
    report [<parameters>]  
    debug [<parameters>]
```

## Parameters

| Parameter | Description                                                              |
|-----------|--------------------------------------------------------------------------|
| -d        | Run the command in the debug mode.                                       |
| help      | Shows the built-in help for the command and for each sub-command.        |
| start     | Starts the <code>probemond</code> daemon.<br>This is the default status. |
| status    | Shows the current status of the <code>probemond</code> daemon.           |
| stop      | Starts the <code>probemond</code> daemon.                                |

| Parameter                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Examples

### Example 1 - Status

```
[Expert@MyGW:0]# probemon status

Probe monitor daemon has been up and running for: 148h, 14m,
50s.

[Expert@MyGW:0]#
```

### Example 2 - Report (without any Network Probes configured)

```
[Expert@MyGW:0]# probemon report

Report:

Monitored probes:

  #   Probe ID   Probe Name           Status      Monitoring Mode   Change   Probe   Probing
Source   Probing Destination
-----
-----

No probes.

Statistics:

-----

Probes up:                0
Probes down:              0
Probes with unknown status: 0
---
Total probes:             0

[Expert@MyGW:0]#
```

# vpn

## Description

Configures VPN settings.

Shows VPN information.

## Syntax

```
vpn
    check_ttm
    debug
    dump_psk
    macutil
    overlap_encdom
    rim_cleanup
    set_snx_encdom_groups
    {tunnelutil | tu}
    ver
```

## Parameters

| Parameter      | Description                                                                                                                                           |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| check_ttm      | Makes sure the specified TTM file is valid.<br>See <a href="#">"vpn check_ttm" on page 1923</a> .                                                     |
| debug          | Controls the debug of <code>vpnd</code> daemon and IKE.<br>See <a href="#">"vpn debug" on page 1924</a> .                                             |
| dump_psk       | Shows hash (SHA256) of peers' pre-shared-keys.<br>See <a href="#">"vpn dump_psk" on page 1936</a> .                                                   |
| macutil        | Shows a generated MAC address for each user name when you use Remote Access VPN with Office Mode.<br>See <a href="#">"vpn macutil" on page 1937</a> . |
| overlap_encdom | Shows all overlapping VPN domains.<br>See <a href="#">"vpn overlap_encdom" on page 1938</a> .                                                         |
| rim_cleanup    | Cleans RIM routes.<br>See <a href="#">"vpn rim_cleanup" on page 1940</a> .                                                                            |

| Parameter                 | Description                                                                                                                                      |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| set_snx_<br>encdom_groups | Controls the encryption domain per usergroup feature for SSL Network Extender.<br>See <a href="#">"vpn set_snx_encdom_groups" on page 1941</a> . |
| tunnelutil  <br>tu        | Launches the TunnelUtil tool, which is used to control VPN tunnels.<br>See <a href="#">"vpn tu" on page 1942</a> .                               |
| ver                       | Shows the major version number and build number of the VPN kernel module.<br>See <a href="#">"vpn ver" on page 1965</a> .                        |

# vpn check\_ttm

## Description

Makes sure the specified TTM file contains valid syntax.

## Syntax

```
vpn check_ttm <Path to TTM file>
```

## Parameters

| Parameter          | Description                                       |
|--------------------|---------------------------------------------------|
| <Path to TTM file> | Specifies the full path and name of the TTM file. |

## Example

```
[Expert@MyGW:0]# find / -name \*.ttm -type f
find: /proc/64899: No such file or directory
/var/opt/CPsuite-R82.10/fw1/conf/fw_client_1.ttm
/var/opt/CPsuite-R82.10/fw1/conf/nemo_client_1.ttm
/var/opt/CPsuite-R82.10/fw1/conf/neo_client_1.ttm
/var/opt/CPsuite-R82.10/fw1/conf/iphone_client_1.ttm
/var/opt/CPsuite-R82.10/fw1/conf/topology_trans_tmpl.ttm
/var/opt/CPsuite-R82.10/fw1/conf/vpn_client_1.ttm
/var/opt/CPsuite-R82.10/fw1/conf/trac_client_1.ttm
... ..
[Expert@MyGW:0]#
[Expert@MyGW:0]# vpn check_ttm /var/opt/CPsuite-R82.10/fw1/conf/trac_client_1.ttm

Summary for the file: trac_client_1.ttm
    result: the file passed the check without any problems

[Expert@MyGW:0]#
```

## vpn debug

## Background

Starting in R81.10, separate daemons handle different VPN connections.

Starting in R81.20, these are the responsibilities of the different daemons - `vpnd`, `iked`, and `cccd`:

### The VPN daemon "`vpnd`"

Handles these VPN connections:

- All connections from non-IKE Remote Access clients (SSL Network Extender, Capsule VPN)
- Multi-Portal traffic (SSL / TLS) to a Security Gateway

The VPN daemon on a Security Gateway listens on these ports:

- Tunnel Test: 18234 (UDP)
- L2TP: 1701 (UDP)
- Check Point RDP: 259 (UDP)
- Session infrastructure manager: 9996 (TCP)

The "`vpnd`" daemon is a child of the FWD daemon (see the `$FWDIR/conf/fwauthd.conf` file on a Security Gateway).

### The IKE daemon "`iked`"

Introduced in the R81.10 version.

Handles these VPN connections:

- All connections from IKE Remote Access clients (for example, Endpoint clients)
- All IKE Site-to-Site connections from peer Security Gateways
- Large Scale VPN (LSV) connections
- Connections from SmartLSM ROBO gateways

Listens on these ports on a Security Gateway:

- IKE: 30500 - 30563 (UDP)
- IKE NAT-T: 34500 - 34563 (UDP)
- Tunnel Test: 48234 - 48297 (UDP)
- Check Point RDP: 30259 - 30322 (UDP)
- L2TP: 31701 - 31764 (UDP)

CLI Syntax to control the IKE daemon "`iked`":

```
vpniked {status | enable | disable | calc <Peer IP address>}
```

Starting in R81.20, there can be a maximum of 64 instances of the "iked" daemon that are calculated based on this formula:

```
Number of IKED instances = (Number of CoreXL Firewall Instances) / (Value of Kernel Parameter 'ike_num_instances_per_daemon')
```

**Note** - You can configure different values for the kernel parameter 'ike\_num\_instances\_per\_daemon'.

### The CCC daemon "cccd"

Introduced in the R81.10 version.

Responsible for the Client Communication Channel (CCC) protocol, while:

- IKE for the same clients runs in the IKE daemon "iked"
- The TLS layer of the CCC protocol for the same clients runs in the VPN daemon "vpnd"

CLI Syntax to control the CCC daemon "cccd":

```
vpncccd {status | enable | disable}
```

The "cccd" daemon is a child of the FWD daemon (see the `$FWDIR/conf/fwauthd.conf` file on a Security Gateway).

## Enabling and Disabling the IKE daemon "iked"

By default, the IKE daemon "iked" is enabled on the Security Gateway.

If you disable the IKE daemon "iked", then in such a legacy mode the VPN daemon "vpnd" handles all VPN connections.

### Procedure to enable the IKE daemon "iked"

| Step | Instructions                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1    | Connect to the command line on the Security Gateway / each Cluster Member.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 2    | Log in to the Expert mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Enabling and Disabling the CCC Daemon "cccd"

By default, the CCC daemon "cccd" is disabled on the Security Gateway.

In such a legacy mode, the VPN daemon `vpnd` handles all VPN connections.

If you enable the CCC daemon "cccd", then this dedicated daemon handles the Client Communication Channel protocol.

### Procedure to enable the CCC daemon "cccd"

| Step | Instructions                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Description

This "vpn debug" command instructs the VPN daemon "vpnd" to write debug messages to these log files:

| File Description       | VPND Log File               | IKED Log File for Each Instance                                                                         | CCCD Log File        |
|------------------------|-----------------------------|---------------------------------------------------------------------------------------------------------|----------------------|
| Main debug output file | \$FWDIR/log/vpnd.elg*       | \$FWDIR/log/iked0.elg<br>\$FWDIR/log/iked1.elg<br>... ..<br>\$FWDIR/log/iked64.elg                      | \$FWDIR/log/cccd.elg |
| IKEv1 output           | \$FWDIR/log/vpnd.ikev1trace | \$FWDIR/log/iked0.ikev1trace<br>\$FWDIR/log/iked1.ikev1trace<br>... ..<br>\$FWDIR/log/iked64.ikev1trace | N/A                  |
| IKEv2 output           | \$FWDIR/log/vpnd.ikev2trace | \$FWDIR/log/iked0.ikev2trace<br>\$FWDIR/log/iked1.ikev2trace<br>... ..<br>\$FWDIR/log/iked64.ikev2trace | N/A                  |

Debugging of the VPN daemon "vpnd" is based on Debug Topics and Debug Levels:

- A Debug Topic is a specific area, on which to perform debugging.  
For example, if the Debug Topic is LDAP, all traffic between the VPN daemon and the LDAP server is written to the log file.  
Check Point Support provides the specific Debug Topics when needed.
- Debug Levels range from 1 (least informative) to 5 (most informative - write all debug messages).

For more information, see [sk180488](#).

In addition, see *"ike debug" on page 1904*.

## Syntax

```
vpn debug
  on [<Debug_Topic>=<Debug_Level>]
  off
  ikeon [-s <Size_in_MB>]
  ikeoff
  trunc [<Debug_Topic>=<Debug_Level>]
  truncon [<Debug_Topic>=<Debug_Level>]
  truncoff
  timeon [<Seconds>]
  timeoff
  ikefail [-s <Size_in_MB>]
  mon
  moff
  say ["String"]
  tunnel [<Level>]
```

## Parameters

| Parameter                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| No Parameters               | Shows the built-in usage.                                                                                                                                                                                                                                                                                                                                                                                                  |

### Return Values

- 0 (zero) for success
- any other value for failure (typically, -1 or 1)

# vpn dump\_psk

## Description

Shows hash (SHA256) of peers' pre-shared-keys.

## Syntax

```
vpn dump_psk
```

# vpn macutil

## Description

Shows a generated MAC address for each user name when you use Remote Access VPN with Office Mode.

This command is applicable only when allocating IP addresses through DHCP.

Remote Access VPN users in Office Mode receive an IP address, which is mapped to a hardware or MAC address.

## Syntax

```
vpn macutil <username>
```

## Example

```
# vpn macutil John  
20-0C-EB-26-80-7D, "John"
```

# vpn overlap\_encdom

## Description

Shows all overlapping VPN domains.

Some IP addresses might belong to two or more VPN domains.

The command alerts for overlapping encryption domains if one or both of the following conditions exist:

- The same VPN domain is defined for both Security Gateways.
- If the Security Gateway has multiple interfaces, and one or more of the interfaces has the same IP address and netmask.

## Syntax

```
vpn overlap_encdom [communities | traditional]
```

## Parameters

| Parameter                | Description                                                                                                                                                                                                                                                    |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>communities</code> | Shows all pairs of objects with overlapping VPN domains, only if the objects (that represent VPN sites) are included in the same VPN community.<br>This parameter is also used, if the same destination IP can be reached through more than one VPN community. |
| <code>traditional</code> | Default parameter.<br>Shows all pairs of objects with overlapping VPN domains.                                                                                                                                                                                 |

## Example

```
# vpn overlap_encdom communities
The objects Paris and London have overlapping encryption domains.
The overlapping domain is:
10.8.8.1 - 10.8.8.1
10.10.8.0 - 10.10.9.255
- This overlapping encryption domain generates a multiple entry points configuration in
MyIntranet and RemoteAccess communities.
- Same destination address can be reached in more than one community (Meshed, Star). This
configuration is not supported.

The objects Paris and Chicago have overlapping encryption domains. The overlapping domain is:
10.8.8.1 - 10.8.8.1
- Same destination address can be reached in more than one community (MyIntranet, NewStar). This
configuration is not supported.

The objects Washington and Tokyo have overlapping encryption domains.
The overlapping domain is:
10.12.10.68 - 10.12.10.68
10.12.12.0 - 10.12.12.127
10.12.14.0 - 10.12.14.255
- This overlapping encryption domain generates a multiple entry points configuration in Meshed,
Star and NewStar communities.
```

# vpn rim\_cleanup

## Description

Cleans RIM routes.

## Syntax

```
vpn rim_cleanup
```

# vpn set\_snx\_encdom\_groups

## Description

Controls the encryption domain per usergroup feature for SSL Network Extender.

## Syntax

```
vpn set_snx_encdom_groups
    off
    on
```

## Parameters

| Parameter | Description                                           |
|-----------|-------------------------------------------------------|
| off       | Disables the encryption domain per usergroup feature. |
| on        | Enables the encryption domain per usergroup feature.  |

# vpn tu

## Description

Launches the `TunnelUtil` tool, which is used to control VPN tunnels.

## General Syntax

```
vpn tu
```

```
vpn tunnelutil
```

## Menu Options

```
[Expert@MyGW:0]# vpn tu
```

```

(2)          * List all IPsec SAs
(3)          List all IKE SAs for a given peer (GW)
(4)          * List all IPsec SAs for a given peer (GW)
(5)          Delete all IPsec SAs for a given peer (GW)
(6)          Delete all IPsec SAs for a given User (Client)
(7)          Delete all IPsec+IKE SAs for a given peer (GW)
(8)          Delete all IPsec+IKE SAs for a given User
(Client)
(9)          Delete all IPsec SAs for ALL peers
(0)          Delete all IPsec+IKE SAs for ALL peers

* To list data for a specific CoreXL instance, append "-i
<instance number>" to your selection.

(Q)          Quit

*****
```

**Note** - When you view Security Associations for a specific VPN peer, you must specify the IP address in dotted decimal notation.

## Advanced Syntax

```
vpn tu [-w]
      help
      conn <options>
      del <options>
      list <options>
      mstats
      tlist <options>
```

## vpn tu conn

### Description

Shows VPN information for the specified traffic connections.

### Syntax for IPv4

```
vpn tu [-w] conn {<Source IPv4 Address> | -} {<Source Port> | -}
{<Destination IPv4 Address> | -} {<Destination Port> | -} [<IPv4
Protocol> | -}]
```

### Syntax for IPv6

```
vpn6 tu [-w] conn {<Source IPv6 Address> | -} {<Source Port> | -}
{<Destination IPv6 Address> | -} {<Destination Port> | -} [<IPv6
Protocol> | -}]
```

### Parameters

| Parameter                                                | Description                                                                                                                                                                                      |

## vpn tu del

### Description

Deletes IPsec Security Associations (SAs) and IKE Security Associations (SAs).

### Syntax for IPv4

```
vpn tu [-w] del
    all
    ipsec
        all
        <IPv4 Address>
        <IPv4 Address> <Username>
        <IPv4 Address> <Local IPv4 Address> <Remote IPv4
Address> <IPv4 Address>
        <IPv4 Address>
        <IPv4 Address> <Username>
        <IPv4 Address> <Local IPv4 Address> <Remote IPv4 Address>
<IPv4 Address>
```

### Syntax for IPv6

```
vpn tu [-w] del
    all
    ipsec
        all
        <IPv6 Address>
        <IPv6 Address>
        <IPv6 Address> <Username>
```

### Parameters

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -w        | Shows various warnings on the screen.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| all       | <p>Deletes all IPsec SAs and IKE SAs for all VPN peers and users.</p> <p> <b>Note</b> - This command is the same as:</p> <ul style="list-style-type: none"> <li>■ In the main <a href="#">"vpn tu" on page 1942</a> menu, the option (0) <b>Delete all IPsec+IKE SAs for ALL peers and users.</b></li> <li>■ In the vpn shell menu, the option <b>tunnels &gt; delete &gt; all &gt; IKE</b> and the option <b>tunnels &gt; delete &gt; all &gt; IPsec.</b></li> </ul> |

| Parameter                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

# vpn tu list

## Description

Shows IPsec SAs and IKE SAs.

## Syntax for IPv4 and IPv6

```
vpn tu [-w] list
    ike
    ipsec
    peer_ike <IP Address>
    peer_ipsec <IP Address>
    probes [{-e | -m | -s}]
    tunnels
```

## Parameters

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## vpn tu mstats

### Description

Shows the distribution of VPN traffic between CoreXL Firewall instances.

For more information, see [sk118097 - MultiCore Support for IPSec VPN in R80.10 and above](#).

### Syntax for IPv4

```
vpn tu [-w] mstats
```

### Syntax for IPv6

```
vpn6 tu [-w] mstats
```

### Parameters

| Item | Description                           |
|------|---------------------------------------|
| -w   | Shows various warnings on the screen. |

### Example for IPv4

```
[Expert@MyGW:0]# vpn tu mstats

Instance# # of inSPIs # of outSPIs
0 182 170
1 184 176
2 191 174
3 215 197
4 237 227
5 191 176
6 180 170
7 190 166
8 171 160
9 199 187
-----
Summary: 1940 1803

[Expert@MyGW:0]#
```

### Example for IPv6

```
[Expert@MyGW:0]# vpn6 tu mstats

Instance# # of inSPIs # of outSPIs
0 238 228
1 224 214
-----
Summary: 462 442

[Expert@MyGW:0]#
```

## vpn tu tlist

### Description

Shows information about VPN tunnels.

### Syntax for IPv4

```
vpn tu [-w] tlist
        {-h | -help}
        [clear]
        [start]
        [state]
        [stop]
        [<Sort Options>]
```

### Syntax for IPv6

```
vpn6 tu [-w] tlist
        {-h | -help}
        [clear]
        [start]
        [state]
        [stop]
        [<Sort Options>]
        [<Output Options>]
```

### Parameters

| Parameter  | Description                                            |
|------------|--------------------------------------------------------|
| -w         | Shows various warnings on the screen.                  |
| -h   -help | Shows the built-in usage.                              |
| clear      | Clears the Tunnel List volume statistics.              |
| start      | Turns on the Tunnel List volume statistics.            |
| state      | Shows the current Tunnel List volume statistics state. |
| stop       | Turns off the Tunnel List volume statistics.           |

| Parameter                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| L2TP         | 0 |

## Explanations About Output

The output of the "vpn tu tlist" command is a table with counters below it.

Each row of the table shows information for one VPN peer.

These fields can appear in the **left column** of the table:

| Field in Left Column | Explanation                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Peer: [IP ADDRESS]   | IP address of the remote peer that communicates with the VPN Gateway through the VPN tunnel.                                                                                                                                                                                                                                                                                      |
| Client public IP     | In a Remote Access VPN tunnel, shows the public IP address of the Remote Access client.                                                                                                                                                                                                                                                                                           |
| Authenticated at     | Date and time when the VPN Gateway finished establishing the tunnel with a Remote Access VPN client.                                                                                                                                                                                                                                                                              |
| Methods              | Encryption methods configured for the VPN tunnel.<br>Examples: <ul style="list-style-type: none"> <li>▪ tunnel type - SSL, ESP</li> <li>▪ encryption type - 3DES, AES-128</li> <li>▪ data integrity algorithm - MD5, SHA1</li> </ul>                                                                                                                                              |
| My TS                | Traffic Selector - Subnets, sections of subnets, or a single IP address behind the VPN Gateway that can be destinations for traffic that passes through the VPN Tunnel.                                                                                                                                                                                                           |
| Peer TS              | Peer Traffic Selector: <ul style="list-style-type: none"> <li>▪ In a Site to Site VPN tunnel, shows subnets, sections of subnets, or a single IP address behind the peer gateway that can be destinations for traffic that passes through the VPN tunnel.</li> <li>▪ In a Remote Access VPN tunnel, shows the IP address of a computer connected to Remote Access VPN.</li> </ul> |
| User                 | In a Remote Access VPN tunnel, shows the username of the remote access user.                                                                                                                                                                                                                                                                                                      |

| ref                   | [INTEGER]                     | The number of connections that the firewall instance handles.                                                                                                                                                                                                                                                                                                                                                                                                       |
|                       | --<br>[INTEGER]/<br>[INTEGER] | <p>The tunnel is disconnected and there is a countdown until termination or re-establishment of the tunnel.</p> <p>The integer before the slash is the number of seconds left in the countdown backwards to 0.</p> <p>The integer after the slash is the total length of the countdown.</p> <p>Example:<br/> "ref: -- 57/60" means the tunnel is disconnected. There are 57 seconds left in a 60-second countdown until tunnel termination or re-establishment.</p> |

These counters appear below "Site-to-Site tunnels are up":

| Field | Explanation                                                                        |
|-------|------------------------------------------------------------------------------------|
| IPsec | The number of Site to Site VPN tunnels of type IPsec connected to the VPN Gateway. |
| NAT-T | The number of Site to Site VPN tunnels of type NAT-T connected to the VPN Gateway. |

These counters appear below "Number of Active Clients":

| Field        | Explanation                                                                                     |
|--------------|-------------------------------------------------------------------------------------------------|
| NAT-T        | The number of Remote Access clients connected to the VPN Gateway in NAT Traversal (NAT-T) mode. |
| Visitor Mode | The number of Remote Access clients connected to the VPN Gateway in Visitor Mode.               |
| SSL          | The number of Remote Access clients connected to the VPN Gateway in SSL mode.                   |
| L2TP         | The number of Remote Access clients connected to the VPN Gateway in L2TP mode.                  |
| strongSwan   | The number of Remote Access clients connected to the VPN Gateway in strongSwan mode.            |

# vpn ver

## Description

Shows the major version number and build number of the VPN kernel module.

## Syntax

```
vpn ver [-k] [-f <filename>]
```

## Parameters

| Parameter | Description                                                          |
|-----------|----------------------------------------------------------------------|
| -k        | Shows the version name and build number and the kernel build number. |
| -f        | Saves the information to the specified text file.                    |

## Example

```
[Expert@MyGW:0]# vpn ver -k
This is Check Point VPN-1(TM) R82.10 - Build 123
kernel: R82.10 - Build 456
[Expert@MyGW:0]#
```

# mcc

## Description

The VPN Multi-Certificate CA (MCC) commands let you manage certificates and Certificate Authorities on a Security Management Server or Domain Management Server:

- Shows Certificate Authorities
- Shows certificates
- Adds certificates
- Deletes certificates

 **Important:**

- Before you run this command, you must close all SmartConsole clients, [Database Tool \(GuiDBEdit Tool\)](#) clients, and "dbedit" clients (see [sk13301](#)) to prevent a lock of the management database. The only exceptions are the "mcc lca" and "mcc show" commands.
- The `mcc` commands require the `cpca` process to be up and running. Run this command:

```
ps auxw | egrep "cpca|COMMAND"
```

- On a Multi-Domain Server, you must run this command in the context of the applicable Domain Management Server:

```
mdsenv <IP Address or Name of Domain Management Server>
```

## Syntax

```
mcc
    -h
    add <options>
    add2main <options>
    del <options>
    lca
    main2add <options>
    show <options>
```

## Parameters

| Parameter | Description               |
|-----------|---------------------------|
| -h        | Shows the built-in usage. |

| Parameter                             | Description                                                                                                         |
|---------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| <code>add &lt;options&gt;</code>      | Adds certificates.<br>See <a href="#">"mcc add" on page 1968</a> .                                                  |

# mcc add

## Description

Adds a certificate stored in DER format in a specified file, as an additional certificate to the specified CA. The new certificate receives an index number higher by one than the highest existing certificate index number.

The new certificate receives an index number higher by one than the highest existing certificate index number.

## Syntax

```
mcc add <CA Name> <Certificate File>
```

**Note**  
On a Multi-Domain Server, you must run this command in the context of the applicable Domain Management Server:

```
mdsenv <IP Address or Name of Domain Management Server>
```

**Important** - Before you run this command, you must close all SmartConsole clients, [Database Tool \(GuiDBEdit Tool\)](#) clients, and "dbedit" clients (see [sk13301](#)) to prevent a lock of the management database.

## Parameters

| Parameter          | Description                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------|
| <CA Name>          | Specifies the name of the CA, as defined in the Management Server database.                                            |
| <Certificate File> | Specifies the path and the name of the certificate file.<br>To show the main certificate of a CA, omit this parameter. |

**Example - Add the certificate stored in the /var/log/Mycert.cer file to the CA called "MyCA"**

```
mcc add MyCA /var/log/Mycert.cer
```

# mcc add2main

## Description

Copies the additional certificate of the specified index number of the specified CA to the main position and overwrites the previous main certificate.

## Syntax

```
mcc add2main <CA Name> <Certificate Index Number>
```

### Note

On a Multi-Domain Server, you must run this command in the context of the applicable Domain Management Server:

```
mdsenv <IP Address or Name of Domain Management Server>
```

**Important** - Before you run this command, you must close all SmartConsole clients, [Database Tool \(GuiDBEdit Tool\)](#) clients, and "dbedit" clients (see [sk13301](#)) to prevent a lock of the management database.

## Parameters

| Parameter                  | Description                                                                 |
|----------------------------|-----------------------------------------------------------------------------|
| <CA Name>                  | Specifies the name of the CA, as defined in the Management Server database. |
| <Certificate Index Number> | Specifies the certificate index number.                                     |

## Example - Copy certificate #1 of a CA called "MyCA" to the main position

```
mcc add2main MyCA 1
```

# mcc del

## Description

Removes the additional certificate of the specified index number from the specified CA.

Greater index numbers (of other additional certificates) are reduced by one.

## Syntax

```
mcc del <CA Name> <Certificate Index Number>
```

### Note

On a Multi-Domain Server, you must run this command in the context of the applicable Domain Management Server:

```
mdsenv <IP Address or Name of Domain Management Server>
```

**Important** - Before you run this command, you must close all SmartConsole clients, [Database Tool \(GuiDBEdit Tool\)](#) clients, and "dbedit" clients (see [sk13301](#)) to prevent a lock of the management database.

## Parameters

| Parameter                  | Description                                                                 |
|----------------------------|-----------------------------------------------------------------------------|
| <CA Name>                  | Specifies the name of the CA, as defined in the Management Server database. |
| <Certificate Index Number> | Specifies the certificate index number.                                     |

## Example - Remove certificate #1 of a CA called "MyCA"

```
mcc del MyCA 1
```

# mcc lca

## Description

Shows all Certificate Authorities (CAs) defined in the Management Server database, with the number of additional CA certificates for each CA.

## Syntax

```
mcc lca
```

### Note

On a Multi-Domain Server, you must run this command in the context of the applicable Domain Management Server:

```
mdsend <IP Address or Name of Domain Management Server>
```

## Example

```
[Expert@MGMT:0]# mcc lca
MCC: Here is a list of the CAs, with the number of additional CA certificates
      1. internal_ca (0)
[Expert@MGMT:0]#
```

# mcc main2add

## Description

Copies the main certificate of the specified CA to an additional position.

The copied certificate receives an index number higher by one than the highest existing certificate index number.

## Syntax

```
mcc main2add <CA Name>
```

### Note

On a Multi-Domain Server, you must run this command in the context of the applicable Domain Management Server:

```
mdsenv <IP Address or Name of Domain Management Server>
```

**Important** - Before you run this command, you must close all SmartConsole clients, [Database Tool \(GuiDBEdit Tool\)](#) clients, and "dbedit" clients (see [sk13301](#)) to prevent a lock of the management database.

## Parameters

| Parameter | Description                                                                 |
|-----------|-----------------------------------------------------------------------------|
| <CA Name> | Specifies the name of the CA, as defined in the Management Server database. |

## Example

The CA called "MyCA" has a main certificate and one additional certificate.

If you run this command, then the CA will have two additional certificates, and additional certificate #2 will be identical to the main certificate:

```
mcc main2add MyCA
```

# mcc show

## Description

Shows details for a specified certificate of a specified CA.

## Syntax

```
mcc show <CA Name> [<Certificate Index Number>]
```

### Note

On a Multi-Domain Server, you must run this command in the context of the applicable Domain Management Server:

```
mdserv <IP Address or Name of Domain Management Server>
```

## Parameters

| Parameter                  | Description                                                                                                        |
|----------------------------|--------------------------------------------------------------------------------------------------------------------|
| <CA Name>                  | Specifies the name of the CA, as defined in the Management Server database.                                        |
| <Certificate Index Number> | Optional.<br>Specifies the certificate index number.<br>To show the main certificate of a CA, omit this parameter. |

## Example 1 - Show certificate #1 of a CA called MyCA

```
mcc show MyCA 1
```

**Example 2 - Show certificate of a CA called "internal\_ca"**

```
[Expert@MGMT:0]# mcc lca
MCC: Here is a list of the CAs, with the number of additional CA certificates
1. internal_ca (0)
[Expert@MGMT:0]#

[Expert@MGMT:0]# mcc show internal_ca

# Mobile Access Commands

For more information about Mobile Access, see the [\*R82.10 Mobile Access Administration Guide\*](#).

# admin\_wizard

## Description

Runs the administration client wizard to test connectivity to websites, Exchange server services, or LDAP server.

 **Note** - This wizard saves its log messages in these files:

- \$CVPNDIR/log/AdminWizardLog.elg
- \$CVPNDIR/log/wizard.elg
- \$CVPNDIR/log/wizardDns
- \$CVPNDIR/log/wizardEstimation
- \$CVPNDIR/log/wizardLdap
- \$CVPNDIR/log/wizardProxy

## Syntax

```
admin_wizard
  cancel
  estimation
  exchange_wizard <Exchange Server Address> <User Name>
  <Password> [<Options>]
  ldap <LDAP server>
  wizard <Web Site Address>
```

 **Important** - On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

## Parameters

| Parameter     | Description                                               |
|---------------|-----------------------------------------------------------|
| No Parameters | Shows the built-in help.                                  |
| cancel        | Kills the administration client wizard that already runs. |
| estimation    | Estimates how many seconds the wizard will run.           |

| Parameter                                                                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <code>ldap &lt;LDAP server&gt;</code>        | Tests connectivity to the specified LDAP server. You can specify the LDAP server by its IP address or hostname.                                                                                                                                                                 |
| <code>wizard &lt;Web Site Address&gt;</code> | Tests connectivity to the specified URL.                                                                                                                                                                                                                                        |

### Example 1 - Check URL accessibility of 'www.checkpoint.com'

```
admin_wizard wizard www.checkpoint.com
```

### Example 2 - Check accessibility to the LDAP server 192.168.0.55

```
admin_wizard ldap 192.168.0.55
```

### Example 3 - Check accessibility for username 'user1' to ActiveSync and EWS on the Exchange server 'exchange.example.com'

```
admin_wizard exchange_wizard exchange.example.com username user1 -
t as,ews
```

# cvpnd\_admin

## Description

Changes the behavior of the Mobile Access **cvpnd** process.

## Syntax

```
cvpnd_admin
  appMonitor status
  clear_kernel_tables
  clear_portal_cache
  debug <options>
  ics_update
  isEnabled
  license <options>
  policy [{graceful | hard}]
  revoke <Certificate Serial Number>
```

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

## Parameters

| Parameter               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| appMonitor<br><options> | <p>Controls the Application Monitor.</p> <p>The Application Monitor is a software component that monitors internal servers to track their up time.</p> <p>If problems are found, a system alert log is created.</p> <p>The available &lt;options&gt; are:</p> <ul style="list-style-type: none"> <li>■ restart - Restarts the Application Monitor.</li> <li>■ start - Start the Application Monitor.</li> <li>■ status - Shows the status of the Application Monitor feature, the applications monitored by the Application Monitor and their status.</li> <li>■ stop - Stops the Application Monitor.</li> </ul> |
| clear_kernel_tables     | Clears all Mobile Access kernel tables.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Parameter                                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

# cvpnd\_settings

## Description

Changes a Mobile Access Gateway local configuration file `$CVPNDIR/conf/cvpnd.C`.

The `cvpnd_settings` commands allow to get attribute values or set them in order to configure the **cvpnd** process.

### Important:

- Changes made by with the `cvpnd_settings` command are **not** saved during the Mobile Access Gateway upgrade. Keep a backup of your `$CVPNDIR/conf/cvpnd.C` file after you make manual changes.
- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

**Warning** - The **cvpnd** process may not start, if you make a mistake in the syntax - attribute names or their values.

## General Syntax

```
cvpnd_settings [<Configuration File>] {get | set | add | listAdd |
listRemove | internal} <Attribute-Name> [<Attribute-Value>]
```

## Syntax for DynamicID Resend

```
cvpnd_settings [<Configuration File>] {set | get}
smsMaxResendRetries [<Number>]
```

## Syntax for Kerberos Authentication

```
cvpnd_settings [<Configuration File>] {set | get} useKerberos
{true | false}
```

```
cvpnd_settings [<Configuration File>] {listAdd | listRemove}
kerberosRealms [<Your AD Name>]
```

## Parameters

Run this command to see the full explanation of the parameters: `cvpnd_settings -h`

| Parameter            | Description                                                                                                                          |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| -h                   | Shows built-in help with full explanation of the parameters.                                                                         |
| <Configuration File> | Specifies the path and the name of configuration file to change.                                                                     |
| get                  | Gets the value of an existing attribute, or values of a list.                                                                        |
| set                  | Sets the value of an attribute.<br>If the specified attribute does not exist in the configuration file, then the command adds it.    |
| add                  | Adds a new attribute.<br>If the specified attribute already exists in the configuration file, then the command does not change it.   |
| listAdd              | Adds the specified attribute to a list.                                                                                              |
| listRemove           | Removes the specified attribute from a list.                                                                                         |
| internal             | Specifies that the command must change the \$CVPNDIR/conf/cvpnd_internal_settings.C file instead of the \$CVPNDIR/conf/cvpnd.C file. |
| <Attribute-Name>     | Specifies the attribute name.                                                                                                        |
| <Attribute-Value>    | Specifies the attribute value.                                                                                                       |
| <Number>             | Specifies the number of SMS resend attempts.                                                                                         |
| <Your AD Name>       | Specifies the Active Directory name.                                                                                                 |

### Examples 1 - Set the value of the attribute 'myFlag' to 1

```
cvpnd_settings set myFlag 1
```

### Examples 2 - See the current value of the attribute 'myFlag'

```
cvpnd_settings get myFlag
```

### Examples 3 - Empty the value of the attribute 'myFlag', or create a new attribute/list 'myFlag'

```
cvpnd_settings set myFlag
```

## Examples 4 - Add the attribute 'myFlag' with the value 'a.example.com' to a list

```
cvpnd_settings listAdd myFlag a.example.com
```

# cvpn\_ver

## Description

Shows the version of the Mobile Access Software Blade.

★ **Best Practice** - Run the "fw ver -k" command to get all version details (see "[fw ver](#)" on page 1296).

## Syntax

```
cvpn_ver
```

i **Important** - On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

## Example

```
[Expert@MyGW:0]# cvpn_ver
This is Check Point Mobile Access R82.10 - Build 123
[Expert@MyGW:0]#
```

# cvpnrestart

## Description

Restarts all Mobile Access Software Blade services.

 **Warning** - While this command does not terminate sessions, it closes all TCP connections. End-users might lose their work.

## Syntax

```
cvpnrestart [--with-pinger]
```

 **Important** - On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

## Parameters

| Parameter     | Description                                                                                                    |
|---------------|----------------------------------------------------------------------------------------------------------------|
| --with-pinger | Restarts the <b>Pinger</b> service, responsible for ActiveSync and Outlook Web Access push mail notifications. |

# cvpnstart

## Description

Starts all Mobile Access Software Blade services, after you stopped them with the "[cvpnstop](#)" [on page 1989](#) command.

## Syntax

```
cvpnstart
```

 **Important** - On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

# cvpnstop

## Description

Stops all Mobile Access Software Blade services.

 **Warning** - While this command does not terminate sessions, it closes all TCP connections. End-users might lose their work.

## Syntax

```
cvpnstop
```

 **Important** - On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

# deleteUserSettings

## Description

Deletes all persistent settings (favorites, cookies, credentials) of one or more end-users.

## Syntax

```
deleteUserSettings [-s] <Username1> [<Username2> ...]
```

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

## Parameters

| Parameter                     | Description                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-s</code>               | Runs in silent mode with no output to the end-user's screen.                                                                                                                                                                                                                                                                                                          |
| <code>&lt;Username&gt;</code> | <p>Specifies the user name, whose settings to delete.</p> <p> <b>Notes:</b></p> <ul style="list-style-type: none"><li>■ When you refer to an internal user, use its username.</li><li>■ When you refer to an LDAP user, use the full DN according to your LDAP settings.</li></ul> |

### Example 1 - Delete an internal user named 'user1'

```
deleteUserSettings [-s] user1
```

### Example 2 - Delete an LDAP user named 'user1', whose DN is 'CN=user1,OU=users,DC=example,DC=com':

```
deleteUserSettings [-s] CN=user1,OU=users,DC=example,DC=com
```

# fwpush

## Description

Sends command interrupts to the **fwpushd** process on the Mobile Access Gateway.

 **Note** - Users get the push notifications only while they are logged in.

## Syntax

```
fwpush
  debug <options>
  del <options>
  info
  print
  send <options>
  unsub <options>
```

 **Important:**

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

## Parameters

| Parameter                                                  | Description                                                                                                             |
|------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <code>debug {off   on   reset   set all all   stat}</code> | Controls the debug of the Mobile Access Push Notifications daemon. For more information, see <a href="#">sk109039</a> . |

| Parameter                                                                                                                                                                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Viewing the details of connected users

```
UserSettingsUtil show_exchange_registered_users
```

### Example output:

```
[Expert@MyGW:0]# UserSettingsUtil show_exchange_registered_users
User Name: CN=JohnD,OU=USERS,OU=RND,OU=PO,OU=USA,DC=AD,DC=CHECKPOINT,DC=COM User Settings id:
c4b6c6fbb0c4xxxxxxxxx265e93e0e372
Push Token: xxxxxxxxxxxx65b48e424023ebxxxxxxxxxca22ea788cfb3cxxxxxxxxxx Device id:
46c5XXXcc1d10b4e18cf5a1xxxxxxxxxx
[Expert@MyGW:0]#
```

### Notes:

- To use the "<Token>" parameter in the "fwpush" commands, use the value of the **Push Token** attribute.  
In the above example:  
xxxxxxxxxxxxxxxx65b48e424023ebxxxxxxxxxca22ea788cfb3cxxxxxxxxxx
- To use the "<Username>" parameter in the "fwpush" commands, use the value of the **CN** attribute.  
In the above example: JohnD
- To use the "<User-UID>" parameter in the "fwpush" commands, use the value of the **User Settings id** attribute.  
In the above example: c4b6c6fbb0c4xxxxxxxxx265e93e0e372

## Example

```
[Expert@MyGW:0]# fwpush send -uid JohnD -msg "Hello - push"
```

# ics\_updates\_script

## Description

Manually starts an Endpoint Security on Demand (ESOD) update on the Mobile Access Gateway.

For more information, see the contents of the `$CVPNDIR/bin/ics_updates_script` file.

## Syntax

```
$CVPNDIR/bin/ics_updates_script <Path to Local ICS Updates  
Package>
```

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

## Parameters

| Parameter                                              | Description                                                                                                             |
|--------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;Path to Local ICS Updates Package&gt;</code> | Specifies the full path to the local ICS Updates package.<br>Do <b>not</b> specify the name of the ICS Updates package. |

# listusers

## Description

Shows a list of end-users connected to the Mobile Access Gateway, along with their source IP addresses.

## Syntax

```
listusers
```

**Important** - On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

## Example

```
[Expert@MyGW:0]# listusers
-----
UserName      | IP
-----
Tom , 192.168.0.51
John , 192.168.0.130
Jane , 192.168.0.7
[Expert@MyGW:0]#
```

# rehash\_ca\_bundle

## Description

Imports all of the Certificate Authority (CA) files from the `$CVPNDIR/var/ssl/ca-bundle/` directory into the Mobile Access trusted CA bundle.

The trusted CA bundle is used when the Mobile Access Gateway accesses an internal server (such as OWA) through HTTPS.

If the SSL server certificate of the internal server is not trusted by the Mobile Access Gateway, the Mobile Access Gateway responds based on the settings for the Internal Web Server Verification feature. The default setting is **Monitor**.

To accept certificates from a specified server, add its server certificate CA to the CA bundle.

## Syntax

```
rehash_ca_bundle
```

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

## Example

```
[Expert@MyGW:0]# rehash_ca_bundle
Doing /opt/CPCvpn-R82.10/var/ssl/ca-bundle/
AC_Ra__z_Certic__mara_S.A..pem => 6f2c1157.0
AOL_Time_Warner_Root_Certification_Authority_1.pem => ed9bb25c.0
... ..
beTRUSTed_Root_CA_-_RSA_Implementation.pem => 16b3fe3c.0
thawte_Primary_Root_CA.pem => 2e4eed3c.0
[Expert@MyGW:0]#
```

# UserSettingsUtil

## Description

Shows details of users connected to the Mobile Access Gateway.

## Syntax

```
UserSettingsUtil show_exchange_registered_users [<Username>]
```

 **Important** - On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

## Parameters

| Parameter  | Description                                                                                                                                                                                                                                                                                                                               |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <Username> | <p>Specifies the user name.</p> <p> <b>Notes:</b></p> <ul style="list-style-type: none"><li>▪ When you refer to an internal user, use its username.</li><li>▪ When you refer to an LDAP user, use the full DN according to your LDAP settings.</li></ul> |

## Example 1 - To show all users

```
[Expert@MyGW:0]# UserSettingsUtil show_exchange_registered_users
User Name: CN=JohnD, OU=USERS, OU=RND, OU=PO, OU=USA, DC=AD, DC=CHECKPOINT, DC=COM User Settings id:
c4b6c6fbb0c4xxxxxxxx265e93e0e372
Push Token: xxxxxxxxxxx65b48e424023ebxxxxxxxxca22ea788cfb3cxxxxxxxx Device id:
46c5XXXccld10b4e18cf5alxxxxxxxx
[Expert@MyGW:0]#
```

## Example 2 - To show an internal user named 'user1'

```
[Expert@MyGW:0]# UserSettingsUtil show_exchange_registered_users user1
```

**Example 3 - To show an LDAP user named 'user1', whose DN is 'CN=user1,OU=users,DC=example,DC=com'**

```
[Expert@MyGW:0]# UserSettingsUtil show_exchange_registered_users CN=user1,OU=users,DC=example,DC=com
```

# Data Loss Prevention Commands

For more information about Data Loss Prevention, see the [\*R82.10 Data Loss Prevention Administration Guide\*](#).

# dlpcmd

## Description

Control the Data Loss Prevention Engine on a Security Gateway.

## Syntax

```
dlpcmd [-s]
        action_by_admin <options>
        getquarantined
        getquarantinedcount
        getquarantinedsize
        ramdisk <options>
```

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

## Parameters

| Parameter                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -s                           | Silent mode - does not print failure messages on the screen.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Example

```
[Expert@MyGW:0]# dlpcmd getquarantined
Printing quarantined mails:
Mail GUID: {8698E6EC-340C-9115-0AB6-F6CA9986147F}; Arrival date: Sun Dec  1 13:38:32 2019; exp
date: Sun Dec  8 13:38:32 2019; sender: dataowner-JOHNDOE;
... ..
[Expert@MyGW:0]#
[Expert@MyGW:0]# dlpcmd action_by_admin 1 {8698E6EC-340C-9115-0AB6-F6CA9986147F} "Released an
Email" "Main Admin"
[Expert@MyGW:0]#
[Expert@MyGW:0]# dlpcmd getquarantined
No quarantined mails
[Expert@MyGW:0]#
```

# VSX Commands

For more information about VSX, see the [R82.10 VSX Administration Guide](#).

# cpconfig

## Description

This command starts the Check Point Configuration Tool.

This tool configures specific settings for the installed Check Point products.

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must connect to the applicable Security Group.

## Syntax on a Security Gateway / Cluster Member in Gaia Clish or the Expert mode

```
cpconfig
```

## Syntax on a Scalable Platform Security Group in Gaia gClish or the Expert mode

```
cpconfig
```

## Menu Options

 **Note** - The options shown depend on the configuration and installed products.

| Menu Option            | Description                                                                                                                                                                                |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Licenses and contracts | Manages Check Point licenses and contracts on this Security Gateway or Cluster Member.                                                                                                     |
| SNMP Extension         | Obsolete. Do <b>not</b> use this option anymore.<br>To configure SNMP, see the <a href="#">R82.10 Gaia Administration Guide</a> - Chapter <i>System Management</i> - Section <i>SNMP</i> . |
| PKCS#11 Token          | Register a cryptographic token, for use by Gaia Operating System.<br>See details of the token, and test its functionality.                                                                 |
| Random Pool            | Configures the RSA keys, to be used by Gaia Operating System.                                                                                                                              |

| Menu Option                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Secure Internal Communication                | <p>Manages SIC on the Security Gateway or Cluster Member. This change requires a restart of Check Point services on the Security Gateway or Cluster Member.</p> <p>For more information, see:</p> <ul style="list-style-type: none"> <li>▪ The <a href="#">R82.10 Security Management Administration Guide</a>.</li> <li>▪ <a href="#">sk65764: How to reset SIC</a>.</li> </ul>                                                                           |

| Check Point CoreXL                                      | <p>Manages CoreXL and Firewall mode on the Security Gateway / Cluster Member / Scalable Platform Security Group.</p> <p>After all changes in CoreXL configuration, you must reboot the Security Gateway / Cluster Member / Security Group. For more information, see the <a href="#">R82.10 Performance Tuning Administration Guide</a>.</p>                                                                                             |
| Automatic start of Check Point Products                 | Shows and controls which of the installed Check Point products start automatically during boot.                                                                                                                                                                                                                                                                                                                                          |
| Exit                                                    | Exits from the Check Point Configuration Tool.                                                                                                                                                                                                                                                                                                                                                                                           |

## Example 1 - Menu on a single Security Gateway

```
[Expert@MySingleGW:0]# cpconfig
This program will let you re-configure
your Check Point products configuration.

Configuration Options:
-----
(1) Licenses and contracts
(2) SNMP Extension
(3) PKCS#11 Token
(4) Random Pool
(5) Secure Internal Communication
(6) Enable cluster membership for this gateway
(7) Check Point CoreXL
(8) Automatic start of Check Point Products

(9) Exit

Enter your choice (1-9) :
```

## Example 2 - Menu on a Cluster Member

```
[Expert@MyClusterMember:0]# cpconfig
This program will let you re-configure
your Check Point products configuration.

Configuration Options:
-----
(1) Licenses and contracts
(2) SNMP Extension
(3) PKCS#11 Token
(4) Random Pool
(5) Secure Internal Communication
(6) Disable cluster membership for this gateway
(7) Enable Check Point Per Virtual System State
(8) Enable Check Point ClusterXL for Bridge Active/Standby
(9) Check Point CoreXL

```

# vsenv

## Description

Changes the shell's current context to the specified Virtual Device.

## Syntax

```
vsenv [{<VSID> | <Name of Virtual Device>}]
```

 **Important** - On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

## Parameters

| Parameter                | Description                                          |
|--------------------------|------------------------------------------------------|
| No Parameters            | Changes the context to the default Virtual Device 0. |
| <VSID>                   | Specifies the Virtual Device by its ID.              |
| <Name of Virtual Device> | Specifies the Virtual Device by its Name.            |

 **Note** - To see the configured Virtual Devices, run the "vsx stat -v" command.

## Example 1 - Changing the context to the default Virtual Device 0

```
[Expert@MyVsxCW:0]# vsenv
Context is set to Virtual Device VSX2_192.168.3.242 (ID 0).
[Expert@MyVsxCW:0]#
```

## Example 2 - Changing the context to the specific Virtual Device

```
[Expert@MyVsxCW:0]# vsenv 2
Context is set to Virtual Device VS2 (ID 2).
[Expert@MyVsxCW:2]#
```

# VSX

## Description

- Shows VSX configuration.
- Fetches VSX configuration.
- Shows and configures Memory Resource Control.

## Syntax

```
vsx
    fetch <options>
    fetch_all_cluster_policies
    fetchvs <options>
    get
    mstat <options>
    resctrl
    showncs <options>
    sicreset
    stat <options>
    unloadall
    vspurge
```

 **Important** - On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

 **Note** - The `fw6 vsx` commands are **not** supported.

## Parameters

| Parameter                               | Description                                                                                                                                                    |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>fetch &lt;options&gt;</code>      | Fetches configuration for VSX Gateway.<br>See <a href="#">"vsx fetch" on page 2014</a> .                                                                       |
| <code>fetch_all_cluster_policies</code> | Fetches security policy for all Virtual Systems and Virtual Routers from cluster peers.<br>See <a href="#">"vsx fetch_all_cluster_policies" on page 2016</a> . |
| <code>fetchvs &lt;options&gt;</code>    | Fetches configuration for a Virtual System.<br>See <a href="#">"vsx fetchvs" on page 2017</a> .                                                                |

| Parameter       | Description                                                                                          |
|-----------------|------------------------------------------------------------------------------------------------------|
| get             | Shows the information about the current VSX context.<br>See <a href="#">"vsx get" on page 2018</a> . |
| mstat <options> | Shows and configures Memory Resource Control.<br>See <a href="#">"vsx mstat" on page 2019</a> .      |

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| resctrl           | <p>From R80.40, the CPU Resource Control is integrated into the CPView utility.</p> <ol style="list-style-type: none"> <li>Go to the context of Virtual System 0: <ul style="list-style-type: none"> <li>In the Expert mode: <div data-bbox="738 412 1460 474" data-label="Text"> <pre>vsenv</pre> </div> </li> <li>In Gaia Clish: <div data-bbox="738 524 1460 586" data-label="Text"> <pre>set virtual-system 0</pre> </div> </li> </ul> </li> <li>Run the CPView: <div data-bbox="657 636 1460 698" data-label="Text"> <pre>cpview</pre> </div> <p>See <a href="#">"cpview" on page 1837</a>.</p> </li> <li>From the top, click:<br/> <b>Advanced &gt; VSX &gt; VSs &gt; Physical-Resources</b> </li> </ol> <p> <b>Notes:</b></p> <ul style="list-style-type: none"> <li>This tab shows the CPU consumption by Virtual Systems and by Virtual Routers.</li> <li>The <b>"CPU %"</b> column shows the percentage of CPU used by all the processes of each Virtual System.<br/> The column shows a percentage of a single CPU (the same behavior as in the <code>"top"</code> command).<br/> Example: <ul style="list-style-type: none"> <li>There are 4 CPU cores on the VSX Gateway.</li> <li>The processes of the Virtual System "VS1" are using: <ul style="list-style-type: none"> <li>30% of CPU 0</li> <li>40% of CPU 1</li> <li>50% of CPU 2</li> <li>10% of CPU 3</li> </ul> </li> </ul> In such case, the <b>"CPU %"</b> column shows 130% for VS1. </li> <li>To get the CPU usage for the VSX Gateway / VSX Cluster Member, divide the <b>"CPU %"</b> value in the <b>Total Resource Consumption</b> section by the number of the CPU cores.</li> </ul> |

| stat <options> | Shows status information for VSX Gateway.<br>See <a href="#">"vsx stat" on page 2025</a> .                                                        |
| unloadall      | Unloads security policy for all Virtual Systems and Virtual Routers.<br>See <a href="#">"vsx unloadall" on page 2028</a> .                        |
| vspurge        | Cleans unused entries for Virtual Devices.<br>Fetches configuration file for Virtual Devices.<br>See <a href="#">"vsx vspurge" on page 2029</a> . |

# vsx fetch

## Description

Fetches the most current configuration files from the Security Management Server or Main Domain Management Server, and applies it to the VSX Gateway.

## Syntax

```
vsx fetch [-v] [-q] [-s] local
```

```
vsx fetch [-v | -q | -s] [-f <Configuration File>]
```

```
vsx fetch [-v | -q] -C "NCS Command"
```

```
vsx fetch [-v | -q | -c | -n | -s] [<Management Server>]
```

**Important** - On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

## Parameters

| Parameter                     | Description                                                                                                                        |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| -c                            | Specifies that this is a VSX Cluster.                                                                                              |
| -n                            | Specifies not to apply the <code>local.vsall</code> , if VSX configuration, as fetched from Management Server, is up-to-date.      |
| -q                            | Specifies to run in quiet mode - shows only summary information.                                                                   |
| -s                            | Specifies to fetch concurrently for multi-processor environment.                                                                   |
| -v                            | Specifies to run in verbose mode - shows detailed information.                                                                     |
| local                         | Reads the configuration file <code>\$FWDIR/state/local/VSX/local.vsall</code> and executes the Network Configuration Script (NCS). |
| -f<br><Configuration<br>File> | Fetches the specified configuration with NCS commands file instead of the default <code>local.vsall</code> file.                   |
| -C<br>"NCS Command"           | Executes the specified NCS command.                                                                                                |

| Parameter                        | Description                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>&lt;Management Server&gt;</i> | <p>Fetches the <code>local.vsall</code> from the specified Management Server (by resolvable hostname, or IP address), replaces and runs it.</p> <p> <b>Note</b> - If you do not specify the Management Server explicitly, the command takes it from the <code>\$FWDIR/conf/masters</code> file on the VSX Gateway.</p> |

## Return Values

- 0 (zero) indicates that the command executed successfully.
- Any other value indicates an error.

## Example

```
[Expert@MyVsxCW:0]# vsx fetch
Fetching VSX Configuration From: 192.168.30.40

Local VSX Configuration is Up-To-Date.
Cleaning un-used Virtual Systems entries (local.vsskeep).

Purge operation succeeded.
Fetching Virtual Systems configuration file (local.vssall).

SecureXL device has been enabled for vsid 1
SecureXL device has been enabled for vsid 2
SecureXL device has been enabled for vsid 3
Virtual Systems configuration file installed successfully
[Expert@MyVsxCW:0]#
```

# vsx fetch\_all\_cluster\_policies

## Description

Fetches security policy for all Virtual Systems and Virtual Routers from cluster peers.

## Syntax

```
vsx fetch_all_cluster_policies [-v]
```

 **Important** - On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

## Parameters

| Parameter | Description                                                    |
|-----------|----------------------------------------------------------------|
| -v        | Specifies to run in verbose mode - shows detailed information. |

## Return Values

- 0 (zero) indicates that the command executed successfully.
- Any other value indicates an error.

# vsx fetchvs

## Description

Fetches configuration file for the specified Virtual Device based on information stored locally on the VSX Gateway.

## Syntax

```
vsx fetchvs [-v | -q] [{<VSID> | <Name of Virtual Device>}]
```

 **Important** - On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

## Parameters

| Parameter                | Description                                                      |
|--------------------------|------------------------------------------------------------------|
| -q                       | Specifies to run in quiet mode - shows only summary information. |
| -v                       | Specifies to run in verbose mode - shows detailed information.   |
| <Name of Virtual Device> | Specifies the name of the Virtual Device.                        |
| <VSID>                   | Specifies the ID of the Virtual Device.                          |

## Return Values

- 0 (zero) indicates that the command executed successfully.
- Any other value indicates an error.

## Example

```
[Expert@MyVsxGW:0]# vsx fetchvs 2
```

# vsx get

## Description

Shows the information about the current VSX context.

## Syntax

```
vsx get
```

 **Important** - On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

## Return Values

- 0 (zero) indicates that the command executed successfully.
- Any other value indicates an error.

## Example

```
[Expert@MyVsxCW:0]# vsx get
Current context is VSX Gateway MyVsxCW (ID 2).
[Expert@MyVsxCW:0]#
```

## vsx mstat

### Description

Shows and configures Memory Resource Control.

Output shows these global memory resources:

| Resource            | Description                               |
|---------------------|-------------------------------------------|
| <b>Memory Total</b> | Total physical memory on the VSX Gateway. |
| <b>Memory Free</b>  | Available physical memory.                |
| <b>Swap Total</b>   | Total of swap memory.                     |
| <b>Swap Free</b>    | Available swap memory.                    |
| <b>Swap-in rate</b> | Total memory swaps per second.            |

In addition:

1. Run the `cpview` command (see ["cpview" on page 1837](#)).
2. From the top, click:

**Advanced > VSX > VSs > Physical-Resources**

### Syntax

```
vsx mstat help
```

```
vsx mstat
    [-vs <VSID>] [unit <Unit>] [sort {<Number> | all}]
    debug
    disable
    enable
    status
    swap <Minutes>
```

 **Important** - On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

### Parameters

| Parameter         | Description               |
|-------------------|---------------------------|
| <code>help</code> | Shows the built-in usage. |

| Parameter                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| No Parameters                                    | Shows the total memory consumption for each Virtual System.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>-vs &lt;VSID&gt;</code>                    | <p>Specifies the Virtual Systems by their IDs.<br/>You can specify:</p> <ul style="list-style-type: none"> <li>▪ One Virtual System.<br/>Example: <code>-vs 1</code></li> <li>▪ Many individual Virtual Systems (separate their IDs with spaces).<br/>Example: <code>-vs 2 3</code></li> <li>▪ A range of Virtual Systems.<br/>Example: <code>-vs 4-6</code></li> </ul> <p> <b>Note</b> - You can combine all the available options (separate them with spaces). Example: <code>-vs 1 4-6</code></p> |
| <code>unit &lt;Unit&gt;</code>                   | <p>Specifies the memory measurement unit shown in the command output:</p> <ul style="list-style-type: none"> <li>▪ B - bytes</li> <li>▪ K - kilobytes</li> <li>▪ M - megabytes (default)</li> <li>▪ G - gigabytes</li> </ul>                                                                                                                                                                                                                                                                                                                                                          |
| <code>sort<br/>{&lt;Number&gt;  <br/>all}</code> | <p>Sorts the Virtual Systems in the output by their memory size.<br/>Specifies the number of Virtual Systems shown in the command output.<br/>Use <code>all</code> to show all Virtual Systems.<br/>If you do not specify this flag, the Virtual Systems in the output are sorted by their VSID.</p>                                                                                                                                                                                                                                                                                  |
| <code>debug</code>                               | Shows memory consumption debug information for each Virtual System by fields, which are defined in the configuration file.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>disable</code>                             | <p>Disables the Memory Resource Control.</p> <p> <b>Note</b> - This change applies immediately and does not require a reboot.</p>                                                                                                                                                                                                                                                                                                                                                                  |
| <code>enable</code>                              | <p>Enables the Memory Resource Control.</p> <p> <b>Note</b> - This change requires a reboot.</p>                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>status</code>                              | Shows the current Memory Resource Control status.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Parameter                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| swap<br><i>&lt;Minutes&gt;</i> | <p>Specifies the swap-in sample rate in minutes.</p> <p>Enter the number of minutes that the system measures memory swaps to determine the swap-in rate.</p> <p>Only integers are valid values.</p> <p>The default swap-in sample rate is 10.</p> <p> <b>Notes:</b></p> <ul style="list-style-type: none"> <li>Swap-in sample rate is a system-wide Linux setting. When you change the value for memory monitoring, all the swap-in rates are calculated according to the new value.</li> <li>When you enable the monitoring memory resources feature, the swap-in rate setting is saved. When you disable the feature, the system restores the saved setting.</li> </ul> |

## Return Values

- 0 (zero) indicates that the command executed successfully.
- Any other value indicates an error.

## Example 1

```
[Expert@MyVsxCW:0]# vsx mstat unit M sort all

VSX Memory Status

[Expert@MyVsxGW:0]#
```

# vsx showncs

## Description

Shows Check Point Network Configuration Script (NCS) for a Virtual Device.

## Syntax

```
vsx showncs {<VSID> | <Name of Virtual Device>}
```

 **Important** - On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

## Parameters

| Parameter                             | Description                               |
|---------------------------------------|-------------------------------------------|
| <i>&lt;Name of Virtual Device&gt;</i> | Specifies the name of the Virtual Device. |
| <i>&lt;VSID&gt;</i>                   | Specifies the ID of the Virtual Device.   |

## Return Values

- 0 (zero) indicates that the command executed successfully.
- Any other value indicates an error.

# vsx sicreset

## Description

Resets SIC for Virtual System or Virtual Router in the current VSX context.

### Notes:

- This operation is **not** supported for the context of VSX Gateway itself (VS0).
- On the Management Server, run the ["cpca\\_client revoke\\_cert" on page 115](#) command to cancel the old certificate.
- In SmartConsole, open the Virtual System object and immediately click **OK**. This action creates a new certificate, and transfers the certificate to the VSX Gateway.

## Syntax

```
vsenv {<VSID> | <Name of Virtual Device>}
```

```
vsx sicreset {<VSID> | <Name of Virtual Device>}
```

 **Important** - On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

## Parameters

| Parameter                             | Description                               |
|---------------------------------------|-------------------------------------------|
| <i>&lt;Name of Virtual Device&gt;</i> | Specifies the name of the Virtual Device. |
| <i>&lt;VSID&gt;</i>                   | Specifies the ID of the Virtual Device.   |

## Return Values

- 0 (zero) indicates that the command executed successfully.
- Any other value indicates an error.

# vsx stat

## Description

Shows status information for VSX Gateway.

## Syntax

```
vsx stat [-l] [-v] [<VSID>]
```

**Important** - On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

## Parameters

| Parameter | Description                                                           |
|-----------|-----------------------------------------------------------------------|
| -l        | Shows a list of all Virtual Devices and their applicable information. |
| -v        | Shows a summary table with all Virtual Devices.                       |
| <VSID>    | Specifies a Virtual Device by its ID.                                 |

## Return Values

- 0 (zero) indicates that the command executed successfully.
- Any other value indicates an error.

**Example 1 - Show a summary table with all Virtual Devices.**

```
[Expert@MyVsxGW:2]# vsx stat -v

# vsx unloadall

## Description

Unloads security policy for all Virtual Systems and Virtual Routers.

See [sk33065: Unloading policy from a VSX Security Gateway](#).

## Syntax

```
vsx unloadall
```

 **Important** - On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

## Return Values

- 0 (zero) indicates that the command executed successfully.
- Any other value indicates an error.

# vsx vspurge

## Description

Removes Virtual Devices that are no longer defined in the management database, but were not removed from the VSX Gateway, because the VSX Gateway was down or disconnected when the management server pushed the updated VSX configuration.

This command cleans all unused Virtual Devices entries (from the NCS `local.vskeep`) and fetches the VSX configuration file (NCS `local.vskeep`) again.

## Syntax

```
vsx vspurge [-q | -v] [-f <purge_file>]
```

 **Important** - On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

## Parameters

| Parameter                          | Description                                                                                     |
|------------------------------------|-------------------------------------------------------------------------------------------------|
| <code>-q</code>                    | Specifies to run in quiet mode - shows only summary information.                                |
| <code>-v</code>                    | Specifies to run in verbose mode - shows detailed information.                                  |
| <code>-f &lt;purge_file&gt;</code> | Specifies the path and the name of the file, in which the command saves the purged information. |

## Return Values

- 0 (zero) indicates that the command executed successfully.
- Any other value indicates an error.

# vsx\_util

## Description

Performs various VSX maintenance tasks.

You run this command from the Expert mode on the Management Server (Security Management Server, or a *Main* Domain Management Server on Multi-Domain Server).

 **Important** - Before you run the `vsx_util` commands:

- Back up the VSX environment. See [sk100395: How to backup and restore VSX gateway](#).
- You must close all SmartConsole clients. Failure to do so may result in a database lock error.
- On a Multi-Domain Security Management Server, you must switch to the context of the **Main** Domain Management Server that manages the VSX Gateway / VSX Cluster object.  
Use the command "`mdsenv <IP Address or Name of Domain Management Server>`".

## Syntax

```
vsx_util -h
```

```
vsx_util <Command> [-s <Mgmt Server>] [-u <UserName>] [-c <Name of VSX Object>] [-m <Name of VSX Cluster Member>]
```

## Parameters

| Parameter                                          | Description                                                                                                          |
|----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------|
| <code>-h</code>                                    | Shows the built-in usage.                                                                                            |
| <code>&lt;Command&gt;</code>                       | Specifies the <code>vsx_util</code> sub-command. See the table below.                                                |
| <code>-s &lt;Mgmt Server&gt;</code>                | Specifies the IP address or resolvable hostname of the Security Management Server, or Main Domain Management Server. |
| <code>-u &lt;UserName&gt;</code>                   | Specifies the administrator username.                                                                                |
| <code>-c &lt;Name of VSX Object&gt;</code>         | Specifies the name of the VSX Gateway or VSX Cluster object.                                                         |
| <code>-m &lt;Name of VSX Cluster Member&gt;</code> | Specifies the name of the VSX Gateway or VSX Cluster Member object.                                                  |

 **Important** - The `vsx_util` command requires you to enter this information:

- IP address or Hostname of the Security Management Server, or *Main* Domain Management Server.
- Management Server Administrator user name and password.
- The applicable VSX object, on which the command operates.
- Most of the `vsx_util` sub-commands are interactive and require additional user input.

## The 'vsx\_util' sub-commands

| Sub-command                        | Description                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| vsx_util<br>add_member             | <p>Adds a new Cluster Member to a VSX Cluster and pushes the VSX Cluster configuration to the new VSX Cluster Member.</p> <p>See <a href="#">"vsx_util add_member" on page 2035</a>.</p> <p>You run this command from the Expert mode on the Management Server (Security Management Server, or a <i>MainDomain</i> Management Server on Multi-Domain Server).</p>                                 |
| vsx_util<br>change_<br>interfaces  | <p>Automatically replaces designated existing interfaces with new interfaces on all Virtual Devices, to which the existing interfaces connect.</p> <p>See <a href="#">"vsx_util change_interfaces" on page 2037</a>.</p> <p>You run this command from the Expert mode on the Management Server (Security Management Server, or a <i>MainDomain</i> Management Server on Multi-Domain Server).</p> |
| vsx_util<br>change_mgmt_<br>ip     | <p>Changes the VSX Management IP address (within the same subnet) of a VSX Gateway or VSX Cluster Member.</p> <p>See <a href="#">"vsx_util change_mgmt_ip" on page 2041</a>.</p> <p>You run this command from the Expert mode on the Management Server (Security Management Server, or a <i>MainDomain</i> Management Server on Multi-Domain Server).</p>                                         |
| vsx_util<br>change_mgmt_<br>subnet | <p>Changes (or adds) the VSX Management IP address of a VSX Gateway or VSX Cluster Member to a new subnet.</p> <p>See <a href="#">"vsx_util change_mgmt_subnet" on page 2042</a>.</p> <p>You run this command from the Expert mode on the Management Server (Security Management Server, or a <i>MainDomain</i> Management Server on Multi-Domain Server).</p>                                    |
| vsx_util<br>change_<br>private_net | <p>Changes the IP address of the Internal Communication Network in a VSX Cluster.</p> <p>See <a href="#">"vsx_util change_private_net" on page 2044</a>.</p> <p>You run this command from the Expert mode on the Management Server (Security Management Server, or a <i>MainDomain</i> Management Server on Multi-Domain Server).</p>                                                             |
| vsx_util<br>convert_<br>cluster    | <p>Converts the VSX Cluster mode between High Availability (default) and Virtual System Load Sharing.</p> <p>See <a href="#">"vsx_util convert_cluster" on page 2046</a>.</p> <p>You run this command from the Expert mode on the Management Server (Security Management Server, or a <i>MainDomain</i> Management Server on Multi-Domain Server).</p>                                            |

| Sub-command                     | Description                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| vsx_util<br>downgrade           | <p>Downgrades the version of a VSX Gateway or VSX Cluster in the management database.</p> <p>See <a href="#">"vsx_util downgrade" on page 2048</a>.</p> <p>You run this command from the Expert mode on the Management Server (Security Management Server, or a <i>MainDomain</i> Management Server on Multi-Domain Server).</p>                                    |
| vsx_util<br>reconfigure         | <p>Restores VSX configuration on a VSX Gateway or VSX Cluster Member.</p> <p>See <a href="#">"vsx_util reconfigure" on page 2049</a>.</p> <p>You run this command from the Expert mode on the Management Server (Security Management Server, or a <i>MainDomain</i> Management Server on Multi-Domain Server).</p>                                                  |
| vsx_util<br>remove_<br>member   | <p>Removes a Cluster Member from a VSX Cluster.</p> <p>See <a href="#">"vsx_util remove_member" on page 2055</a>.</p> <p>You run this command from the Expert mode on the Management Server (Security Management Server, or a <i>MainDomain</i> Management Server on Multi-Domain Server).</p>                                                                      |
| vsx_util<br>show_<br>interfaces | <p>Shows configuration of selected interfaces - interface types, connections to Virtual Devices, and IP addresses.</p> <p>See <a href="#">"vsx_util show_interfaces" on page 2056</a>.</p> <p>You run this command from the Expert mode on the Management Server (Security Management Server, or a <i>MainDomain</i> Management Server on Multi-Domain Server).</p> |
| vsx_util<br>upgrade             | <p>Upgrades the version of a VSX Gateway or VSX Cluster in the management database.</p> <p>See <a href="#">"vsx_util upgrade" on page 2060</a>.</p> <p>You run this command from the Expert mode on the Management Server (Security Management Server, or a <i>MainDomain</i> Management Server on Multi-Domain Server).</p>                                        |
| vsx_util<br>view_vs_conf        | <p>Shows configuration of a Virtual Device on the Management Server versus the VSX Gateway or VSX Cluster.</p> <p>See <a href="#">"vsx_util view_vs_conf" on page 2061</a>.</p> <p>You run this command from the Expert mode on the Management Server (Security Management Server, or a <i>MainDomain</i> Management Server on Multi-Domain Server).</p>            |

| Sub-command      | Description                                                                                                                                                                                                                                                                                                                                           |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| vsx_util<br>vsls | Shows the configuration menu for Virtual System Load Sharing - see status, redistribute, export and import configuration.<br>See " <a href="#">vsx_util vsls</a> " on page 2065.<br>You run this command from the Expert mode on the Management Server (Security Management Server, or a <i>MainDomain</i> Management Server on Multi-Domain Server). |

## Notes

- This command writes its messages to the `vsx_util_YYYYMMDD_HH_MM.log` file on the Management Server:

- On a Security Management Server:

```
$FWDIR/log/vsx_util_YYYYMMDD_HH_MM.log
```

- On a Multi-Domain Server - if executed the command in the MDS context:

```
/opt/CPsuite-R82.10/fw1/log/vsx_util_YYYYMMDD_HH_MM.log
```

- On a Multi-Domain Server - if executed the command in the context of a Domain Management Server:

```
/opt/CPmds-R82.10/customers/<Name of Domain Management Server>/CPsuite-R82.10/fw1/log/vsx_util_YYYYMMDD_HH_MM.log
```

- If it is necessary to exit from the `vsx_util` command's menu, press the **CTRL C** keys.

**Important** - Do not press these keys, if this command already started to perform a change. If you press these keys during the operation, the command does not save its log file.

# vsx\_util add\_member

## Description

Adds a new Cluster Member to a VSX Cluster and pushes the VSX Cluster configuration to the new VSX Cluster Member.

 **Important** - Before you run the `vsx_util` commands:

- Back up the VSX environment. See [sk100395: How to backup and restore VSX gateway](#).
- You must close all SmartConsole clients. Failure to do so may result in a database lock error.
- On a Multi-Domain Security Management Server, you must switch to the context of the **Main** Domain Management Server that manages the VSX Gateway / VSX Cluster object.

Use the command "`mdsenv <IP Address or Name of Domain Management Server>`".

## Syntax

```
vsx_util add_member
```

## Required Input

- The applicable VSX Cluster object.
- Name of the new VSX Cluster Member.
- IP address for the management interface.
- IP address for the synchronization interface.
- The one-time Activation Key (SIC activation key)

## Comments

- Execute the command and follow the instructions on the screen.
- After the command adds a new Cluster Member to the management database, the command prompts you to reconfigure the new VSX Cluster Member (to push the VSX Cluster configuration to it).
  - If you enter "y" to reconfigure the new VSX Cluster Member at this time, then the *"vsx\_util reconfigure" on page 2049* operation starts automatically on the new VSX Cluster Member.
  -  **Important** - You must reboot the new VSX Cluster Member after the reconfigure operation finishes.
  - If you enter "n" to cancel the reconfigure operation on the new VSX Cluster Member at this time, then later you must manually run the *"vsx\_util reconfigure" on page 2049* command for the new VSX Cluster Member.

# vsx\_util change\_interfaces

## Description

Automatically replaces designated existing interfaces with new interfaces on all Virtual Devices, to which the existing interfaces connect.

This command is useful when converting a deployment to use Link Aggregation, especially where VLANs connect to many Virtual Devices.

 **Important** - Before you run the `vsx_util` commands:

- Back up the VSX environment. See [sk100395: How to backup and restore VSX gateway](#).
- You must close all SmartConsole clients. Failure to do so may result in a database lock error.
- On a Multi-Domain Security Management Server, you must switch to the context of the **Main** Domain Management Server that manages the VSX Gateway / VSX Cluster object.  
Use the command `"mdsensv <IP Address or Name of Domain Management Server>"`.

## Syntax

```
vsx_util change_interfaces
```

## Required Input

- The applicable VSX Gateway or VSX Cluster object.
- Where to apply the change (Management Server only, or Management Server and VSX Gateway / VSX Cluster Members).
- Name of the interface to be replaced.
- Name of the new (replacement) interface.

## Comments

- Execute the command and follow the instructions on the screen.
- This command supports the resume feature.
- You can use this command to migrate a VSX deployment from an Open Server to a Check Point appliance by using the **Management Only** mode.
- Refer to the **Notes** section below for additional information.

## Procedure

| Step | Instructions                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1    | Close all SmartConsole clients that are connected to the Security Management Server or Domain Management Servers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 2    | Connect to the command line on the Management Server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 3    | Log in to the Expert mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 4    | On Multi-Domain Server, go to the context of the <i>Main</i> Domain Management Server that manages the applicable VSX Gateway (VSX Cluster) object: <div>mdsenv &lt;IP address or Name of Domain Management Server&gt;</div>                                                                                                                                                                                                                                                                                                                                                                               |

| 14   | <p>Reboot the VSX Gateway (all VSX Cluster Members).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Notes

- The option **"Apply changes to the management database and to the VSX Gateway/Cluster members immediately"** verifies connectivity between the Management Server and the VSX Gateway or VSX Cluster Members. In the event of a connectivity failure one of the following actions occur:

1. If **all** of the newly changed interfaces fail to establish connectivity, the process terminates unsuccessfully.
2. If one or more interfaces successfully establish connectivity, while one or more other interfaces fail, you may optionally continue the process.

In this case, those interfaces for which connectivity was established successfully will be changed.

For those interfaces that failed, you must then resolve the issue and then run the ["vsx\\_util reconfigure" on page 2049](#) command to complete the process.

- If you select the option **"Apply changes to the management database only"**, you can select one of these:
  - Another interface from list (if any are available).
  - Option to add a new interface.

# vsx\_util change\_mgmt\_ip

## Description

Changes the VSX Management IP address of a VSX Gateway or VSX Cluster Member.

This command changes the Management IP address within the same subnet.

For more information, see [sk92425](#).

**Important** - Before you run the `vsx_util` commands:

- Back up the VSX environment. See [sk100395: How to backup and restore VSX gateway](#).
- You must close all SmartConsole clients. Failure to do so may result in a database lock error.
- On a Multi-Domain Security Management Server, you must switch to the context of the **Main** Domain Management Server that manages the VSX Gateway / VSX Cluster object.

Use the command `"mdsensv <IP Address or Name of Domain Management Server>"`.

## Syntax

```
vsx_util change_mgmt_ip
```

## Required Input

- The applicable VSX Cluster object.
- The applicable VSX Cluster Member object.
- New management IP address.

## Comments

- Execute the command and follow the instructions on the screen.

# vsx\_util change\_mgmt\_subnet

## Description

Changes the VSX Management IP address of a VSX Gateway or VSX Cluster Member.

This command changes the Management IP address from the current subnet to a different subnet.

For more information, see [sk92425](#).

**Important** - Before you run the `vsx_util` commands:

- Back up the VSX environment. See [sk100395: How to backup and restore VSX gateway](#).
- You must close all SmartConsole clients. Failure to do so may result in a database lock error.
- On a Multi-Domain Security Management Server, you must switch to the context of the **Main** Domain Management Server that manages the VSX Gateway / VSX Cluster object.  
Use the command "`mdsensv <IP Address or Name of Domain Management Server>`".

## Syntax

```
vsx_util change_mgmt_subnet
```

## Required Input

- The applicable VSX Gateway or VSX Cluster object.
- New management IPv4 address.
- New management IPv4 netmask.
- New management IPv6 address.
- New management IPv6 prefix.
- New IPv4 default gateway.
- New IPv6 default gateway.

## Comments

- Execute the command and follow the instructions on the screen.
- This command updated only routes that were automatically generate.  
You must remove and/or change all manually created routes that use the previous management subnet.
- You must reboot the VSX Gateway (all VSX Cluster Members) after the command finishes.

# vsx\_util change\_private\_net

## Description

Changes the IP address of the Internal Communication Network in a VSX Cluster (cluster private network).

 **Important** - Before you run the `vsx_util` commands:

- Back up the VSX environment. See [sk100395: How to backup and restore VSX gateway](#).
- You must close all SmartConsole clients. Failure to do so may result in a database lock error.
- On a Multi-Domain Security Management Server, you must switch to the context of the **Main** Domain Management Server that manages the VSX Gateway / VSX Cluster object.

Use the command "`mdsenv <IP Address or Name of Domain Management Server>`".

## Syntax

```
vsx_util change_private_net
```

## Required Input

- The applicable VSX Cluster object.
- New IPv4 address for the cluster private network.
- New IPv4 netmask for the cluster private network.
- New IPv6 address and prefix for the cluster private network.

## Comments

- Run the command and follow the instructions on the screen.
- The IP address of the Internal Communication Network must be unique.

This IP address must **not** be used anywhere in your environment, including the Virtual Devices on this VSX Cluster.

- The illegal IPv4 addresses are: 0.0.0.0, 127.0.0.0, and 255.255.255.255
- For IPv4 address, the network mask must be one of these:
  - 255.255.0.0, or /16
  - 255.255.128.0, or /17
  - 255.255.192.0, or /18
  - 255.255.224.0, or /19
  - 255.255.240.0, or /20
  - 255.255.248.0, or /21
  - 255.255.252.0, or /22 (this is the default)
- For IPv6 address, the new prefix must be /80.

# vsx\_util convert\_cluster

## Description

Converts the VSX Cluster mode between High Availability (default) and Virtual System Load Sharing.

 **Important** - Before you run the `vsx_util` commands:

- Back up the VSX environment. See [sk100395: How to backup and restore VSX gateway](#).
- You must close all SmartConsole clients. Failure to do so may result in a database lock error.
- On a Multi-Domain Security Management Server, you must switch to the context of the **Main** Domain Management Server that manages the VSX Gateway / VSX Cluster object.  
Use the command "`mdsensv <IP Address or Name of Domain Management Server>`".

 **Important:**

- The only mode available for a VSX Cluster that was installed as R81.10 and higher is **Virtual System Load Sharing (VSLS)**.
- The **High Availability** mode is available only if you upgrade a VSX Cluster from R81 or lower to R82.10.  
You can also convert a VSLS cluster to the High Availability mode (see the [R82.10 VSX Administration Guide](#) > section "Changing the VSX Cluster Type").
- It is not supported to run the `vsx_util convert_cluster` command to convert a VSX Cluster from the High Availability mode to the VSLS mode when the VSX Cluster contains a Virtual Switch that is not assigned to any physical interface or to a VLAN interface.

## Syntax

```
vsx_util convert_cluster
```

## Required Input

- The applicable VSX Cluster object.
- The ClusterXL mode (case sensitive).

## Comments

- Execute the command and follow the instructions on the screen.
- When you convert from Virtual System Load Sharing to High Availability:

- All Virtual Systems are **Active** on the same VSX Cluster Member by default.
- Peer Virtual Systems are **Standby** on other VSX Cluster Members.

# vsx\_util downgrade

## Description

Downgrades the version of a VSX Gateway or VSX Cluster in the management database.

 **Important** - You can use this command only if you did **not** make any configuration changes after you used the "vsx\_util upgrade" command.

 **Important** - *Before* you run the vsx\_util commands:

- Back up the VSX environment. See [sk100395: How to backup and restore VSX gateway](#).
- You must close all SmartConsole clients. Failure to do so may result in a database lock error.
- On a Multi-Domain Security Management Server, you must switch to the context of the **Main** Domain Management Server that manages the VSX Gateway / VSX Cluster object.

Use the command "mdsensv <IP Address or Name of Domain Management Server>".

## Syntax

```
vsx_util downgrade
```

## Required Input

- The applicable VSX Gateway or VSX Cluster object.
- The applicable Check Point version.

## Comments

- Used only to revert the upgraded VSX Gateway or VSX Cluster object.
- Execute the command and follow the instructions on the screen.
- To deploy the version change to the VSX Cluster Members, you must run the "[vsx\\_util reconfigure](#)" on page 2049 command.

# vsx\_util reconfigure

## Description

Restores VSX configuration on a VSX Gateway or VSX Cluster Member (for example, after you perform clean install after a system failure).

## Syntax

```
vsx_util reconfigure
```

 **Important** - Before you run the `vsx_util` commands:

- Back up the VSX environment. See [sk100395: How to backup and restore VSX gateway](#).
- You must close all SmartConsole clients. Failure to do so may result in a database lock error.
- On a Multi-Domain Security Management Server, you must switch to the context of the **Main** Domain Management Server that manages the VSX Gateway / VSX Cluster object.  
Use the command `"mdsensv <IP Address or Name of Domain Management Server>"`.

 **Important** - Before you run this command on the Management Server, you must configure specific settings on the cleanly installed VSX Gateway or VSX Cluster Member as they were:

- IP address of Gaia management interface
- Enable IPv6 support in Gaia
- Configure the applicable interfaces (Bond, VLAN, and so on)
- Configure kernel parameters and their values:
  - `$FWDIR/boot/modules/fwkernel.conf`
  - `$PPKDIR/conf/simkernel.conf`
- Configure CoreXL:
  - Number of CoreXL Firewall instances (for IPv4 and IPv6) in the context of VS0 (run the `cpconfig` command and select the option **Check Point CoreXL**)
  - `$FWDIR/conf/fwaffinity.conf`

 **Important** - While the `"vsx_util reconfigure"` command is running on the Management Server, it is not supported to make any configuration changes on the Scalable Platform Security Group. You must wait until all Security Group Members and Virtual Systems are up and running (Limitation ID 01812597).

## Required Input

- The applicable VSX Gateway or VSX Cluster object.
- The one-time Activation Key (SIC activation key).

## Comments

- Execute the command and follow the instructions on the screen.
- The new VSX Gateway or VSX Cluster Member:

- Must be a *new* installation.

You cannot use a VSX Gateway or VSX Cluster Member with a previous VSX configuration.

- Must have the same hardware specifications as the original.

Most importantly, it must have *at least* the same number of interfaces.

- Must have the same Gaia OS configuration as the original.

Most importantly, it must have the same VSX Management IP address.

## Limitations

The reconfigure process does **not** restore the local configuration that was performed on VSX Gateway or VSX Cluster Member itself (because this configuration is not stored on the Management Server).

-  **Important** - After the reconfigure process is complete and you rebooted VSX Gateway or VSX Cluster Member, you must manually configure these settings from scratch or from backed up files.

These settings and files are **not** restored during the reconfigure process and you must manually configure them again:

- **Per Virtual System State** - run the `"cpconfig"` command and examine the option "Per Virtual System State". The title of this option must be the same on each VSX Cluster Member - either "Enable Check Point Per Virtual System State" or "Disable Check Point Per Virtual System State". To change this configuration, enter the number of this option and follow the instructions on the screen.

 **Note** - Do not change the value of the kernel parameter `"fwha_enable_state_machine_by_vs"` in the `$FWDIR/boot/modules/fwkern.conf` file. The VSX Cluster changes this value automatically.

- Any OS configuration (for example, DNS, NTP, DHCP, Dynamic Routing, DHCP Relay, and so on).
- Backup files and Gaia snapshots saved in the past on the VSX Gateway or VSX Cluster Member.
- Any settings manually defined in various configuration files on the VSX Gateway or VSX Cluster Member.
- Any Check Point configuration files.

 **Note** - Some of these files do not exist by default. Some files are configured on each VSX Gateway and VSX Cluster Member, and some files are configured for each Virtual System.

### List of the most important files

 **Note** - Some of these files do not exist by default. Some files are configured on each VSX Gateway and VSX Cluster Member, and some files are configured in the context of each Virtual System.

This list is sorted alphabetically.

- `$CVPNDIR/conf/cvpnd.C`
- `$FWDIR/boot/modules/fwkern.conf`
- `$FWDIR/conf/cpha_bond_ls_config.conf`

- \$FWDIR/conf/cpha\_specific\_vlan\_data.conf (see [sk92784](#))
- \$FWDIR/conf/discntd.if
- \$FWDIR/conf/fw\_fast\_accel\_export\_configuration.conf (see [sk156672](#))
- \$FWDIR/conf/fwaffinity.conf
- \$FWDIR/conf/fwauthd.conf
- \$FWDIR/conf/hsm\_configuration.C
- \$FWDIR/conf/identity\_broker.C
- \$FWDIR/conf/ipassignment.conf
- \$FWDIR/conf/local.arp (see [sk30197](#))
- \$FWDIR/conf/malware\_config
- \$FWDIR/conf/prioq.conf (see [sk105762](#))
- \$FWDIR/conf/rad\_conf.C
- \$FWDIR/conf/synatk.conf
- \$FWDIR/conf/te.conf
- \$FWDIR/conf/thresholds.conf
- \$FWDIR/conf/trac\_client\_1.ttm
- \$FWDIR/conf/vsaffinity\_exception.conf
- \$PPKDIR/conf/simkern.conf
- /var/ace/sdconf.rec
- /var/ace/sdopts.rec
- /var/ace/sdstatus.12
- /var/ace/securid

## Example

This example shows how the VSX configuration is restored on a VSX Cluster Member.

```
[Expert@MDS:0]# vsx_util reconfigure

*****
* Note: the operation you are about to perform changes the information in the management *
* database. Back up the database before continuing. *
*****

Enter Security Management Server/main Domain Management Server IP address (Hit 'ENTER' for
'localhost'): 192.168.3.240
Enter Administrator Name: *****
Enter Administrator Password: *****
Select VSX gateway/cluster object name:
  1)    VSX_Cluster
Select: 1

Select VSX member name to reconfigure:
  1)    VSX1_192.168.3.241
  2)    VSX2_192.168.3.242
Select: 1
You are about to perform reconfigure on VSX gateway/cluster, please read sk97552.
Are you sure you want to continue [y/n]? y
Enter Activation Key:
Retype Activation Key:

```

```
===== SUMMARY =====
---- Reconfigure gateway operation completed successfully

*****
IMPORTANT:
  When you are managing a VSX cluster,
  make sure that the new reconfigured member has the same number of
  IPv4, and IPv6 firewall instances as the other VSX cluster members.
  Run cpconfig command to show and edit CoreXL settings.
NOTE:
  In case of adding a new cluster member to a VSX Cluster,
  while using 'ClusterXL Virtual System Load Sharing'
  make sure to run 'vsx_util vsls' after rebooting the
  gateway in order for the Virtual Systems to become active
  on the newly added VSX cluster member.

IMPORTANT: Please reboot the gateway

[Expert@MDS:0]#
```

# vsx\_util remove\_member

## Description

Removes a Cluster Member from a VSX Cluster.

**Important** - Before you run the `vsx_util` commands:

- Back up the VSX environment. See [sk100395: How to backup and restore VSX gateway](#).
- You must close all SmartConsole clients. Failure to do so may result in a database lock error.
- On a Multi-Domain Security Management Server, you must switch to the context of the **Main** Domain Management Server that manages the VSX Gateway / VSX Cluster object.  
Use the command `"mdsensv <IP Address or Name of Domain Management Server>"`.

## Syntax

```
vsx_util remove_member
```

## Required Input

- The applicable VSX Cluster object.
- The applicable VSX Cluster Member object.

## Comments

- Before you run this command:
  - Make sure to remove (detach) the license from the VSX Cluster Member.
  - Make sure to run the ["cphastop" on page 1435](#) command to avoid unexpected failover from the VSX Cluster Member.
  - Make sure to disconnect the VSX Cluster Member from all networks, except from the Management Server.
- Execute the command and follow the instructions on the screen.

# vsx\_util show\_interfaces

## Description

Shows configuration of selected interfaces - interface types, connections to Virtual Devices, and IP addresses.

The command shows the information on the screen and also saves it to the `interfacesconfig.csv` file in the current working directory.

 **Important** - On a Multi-Domain Security Management Server, you must switch to the context of the **MainDomain** Management Server that manages the VSX Gateway / VSX Cluster object.

Use the command "`mdsensv <IP Address or Name of Domain Management Server>`".

## Syntax

```
vsx_util show_interfaces
```

## Required Input

- The applicable VSX Gateway or VSX Cluster object.
- Which interfaces to show:

| Menu Option                | Description                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1) All Interfaces          | Shows all interfaces (Physical and Warp).                                                                                                                                                                                                                                                                                                                                          |
| 2) All Physical Interfaces | Shows only Physical interfaces.                                                                                                                                                                                                                                                                                                                                                    |
| 3) All Warp Interfaces     | Shows only Warp interfaces.                                                                                                                                                                                                                                                                                                                                                        |
| 4) A Specific Interface    | <p>Prompts you to enter the name of the specific interface to show.</p> <p> <b>Note</b> - You cannot specify a VLAN tag as a parameter. You can, however, specify an interface used as a VLAN (without the tag) to see all VLAN tags associated with that interface. See the example below.</p> |

## Example

```
[Expert@MGMT:0]# vsx_util show_interfaces
Enter Security Management Server/main Domain Management Server IP address (Hit 'ENTER' for
'localhost'): 172.16.16.240
Enter Administrator Name: admin
Enter Administrator Password:

Select VSX gateway/cluster object name:
  1)    VSX_Cluster_1
  2)    VSX_Cluster_2
  3)    VSX_GW_1
  4)    VSX_GW_2
Select: 1

Which interface would you like to display?
  1)    All Interfaces
  2)    All Physical Interfaces
  3)    All Warp Interfaces
  4)    A Specific Interface
Enter your choice: 1

# vsx\_util upgrade

## Description

Upgrades the version of a VSX Gateway or VSX Cluster in the management database.

 **Important** - *Before* you run the `vsx_util` commands:

- Back up the VSX environment. See [sk100395: How to backup and restore VSX gateway](#).
- You must close all SmartConsole clients. Failure to do so may result in a database lock error.
- On a Multi-Domain Security Management Server, you must switch to the context of the **Main** Domain Management Server that manages the VSX Gateway / VSX Cluster object.  
Use the command `"mdsend <IP Address or Name of Domain Management Server>"`.

## Syntax

```
vsx_util upgrade
```

## Required Input

- The applicable VSX Gateway or VSX Cluster object.
- The applicable Check Point version.

## Comments

- Execute the command and follow the instructions on the screen.
- After the command finishes, you must run the ["vsx\\_util reconfigure" on page 2049](#) command.
- To revert this upgrade, run the ["vsx\\_util downgrade" on page 2048](#) command.

# vsx\_util view\_vs\_conf

## Description

Compares the configuration of all Virtual Devices on the Management Server and the actual configuration on the VSX Gateway or VSX Cluster Members.

**Important** - On a Multi-Domain Security Management Server, you must switch to the context of the **Main** Domain Management Server that manages the VSX Gateway / VSX Cluster object.

Use the command "*mdsensv <IP Address or Name of Domain Management Server>*".

## Syntax

```
vsx_util view_vs_conf
```

## Required Input

- The applicable VSX Gateway or VSX Cluster object.
- The applicable Virtual Device object.

## Example

```
[Expert@MGMT:0]# vsx_util view_vs_conf
Enter Security Management Server/main Domain Management Server IP address (Hit 'ENTER' for
'localhost'): 172.16.16.240
Enter Administrator Name: admin
Enter Administrator Password:
```

Select VSX gateway/cluster object name:

- 1) VSX\_Cluster\_1
- 2) VSX\_Cluster\_2
- 3) VSX\_GW
- 4) VSX\_GW\_2

Select: 1

Select Virtual Device object name:

- 1) VS1
- 2) VS2
- 3) VS3
- 4) VSX\_Cluster

Select: 1

Type: Virtual System

Interfaces configuration table:

| Interfaces |                                        | Mgmt |       | VSX GW(s) |  |
|------------|----------------------------------------|------|-------|-----------|--|
| Name       | IP / Mask length                       |      | mem 1 | mem2      |  |
| eth2       | v4 10.0.0.0/24 v6 2001:db8::abc::1/64  | V    | V     | V         |  |
| eth3       | v4 10.10.10.10/24 v6 2001:db8::3121/64 | V    | V     | V         |  |

Interfaces Table Legend:

V - Interface exists on the gateway and matches management information (if defined on the management).  
 - - Interface does not exist on the gateway.  
 N/A - Fetching Virtual Device configuration from the gateway failed.  
 !IP - Interface exists on the gateway, but there is an IP address mismatch.  
 !MASK - Interface exists on the gateway, but there is a Net Mask mismatch.

Routing table:

| Ipv4 Routes               |         | Mgmt      |      | VSX GW(s) |   |
|---------------------------|---------|-----------|------|-----------|---|

+-----+-----+-----+-----+-----+
```

Routing Table Legend:

- V - Route exists on the gateway and matches management information (if defined on the management).
- - Route does not exist on the gateway.
- N/A - Fetching Virtual Device configuration from the gateway failed.
- !NH - Route exists on the gateway, but there is a Next Hop mismatch.

Note: Routes can be created automatically on the gateways by the Operating System. Therefore, routes that appear on all gateways, but are not defined on the management, do not necessarily indicate a problem.

Logging details are available at /opt/CPsuite-R82.10/fw1/log/vsx\_util\_20210625\_18\_11.log

[Expert@MGMT:0]#

# vsx\_util vsls

## Description

Shows the configuration menu for Virtual System Load Sharing - status, redistribute, export, and import of configuration.

 **Important** - Before you run the `vsx_util` commands:

- Back up the VSX environment. See [sk100395: How to backup and restore VSX gateway](#).
- You must close all SmartConsole clients. Failure to do so may result in a database lock error.
- On a Multi-Domain Security Management Server, you must switch to the context of the **Main** Domain Management Server that manages the VSX Gateway / VSX Cluster object.  
Use the command "`mdsenv <IP Address or Name of Domain Management Server>`".

 **Important:**

- The only mode available for a VSX Cluster that was installed as R81.10 and higher is **Virtual System Load Sharing (VSLS)**.
- The **High Availability** mode is available only if you upgrade a VSX Cluster from R81 or lower to R82.10.  
You can also convert a VSLS cluster to the High Availability mode (see the [R82.10 VSX Administration Guide](#) > section "Changing the VSX Cluster Type").

## Syntax

```
vsx_util vsls
```

## Required Input

- The applicable VSX Cluster object.
- The applicable redistribution option.

## Comments

- Execute the command and follow the instructions on the screen.
- If the command output shows "Operation not allowed. Object is not a Virtual System Load Sharing cluster.", then run the "[vsx\\_util convert\\_cluster](#)" on page 2046 command.

## Example

```
[Expert@MGMT:0]# vsx_util vsls
Enter Security Management Server/main Domain Management Server IP address (Hit 'ENTER' for
'localhost'): 172.16.16.240
Enter Administrator Name: admin
Enter Administrator Password:

Select VSX gateway/cluster object name:
  1)    VSX_Cluster_1
  2)    VSX_Cluster_2
  3)    VSX_GW_1
  4)    VSX_GW_2
Select: 1

VS Load Sharing - Menu
-----
1. Display current VS Load sharing configuration
2. Distribute all Virtual Systems so that each cluster member is equally loaded
3. Set all VSes active on one member
4. Manually set priority and weight
5. Toggle VSLS mode between Active Up and Primary Up
6. Import configuration from a file
7. Export configuration to a file
8. Exit

Enter redistribution option (1-8) [1]:
```

# vsx\_provisioning\_tool

This section describes the **VSX Provisioning Tool** (the `vsx_provisioning_tool` command).

## Description

This tool allows the VSX administrator to add and remove Virtual Devices (Virtual Systems, Virtual Routers, Virtual Switches), interfaces and routes from the command line of a Security Management Server or Domain Management Server.

This allows the automation of the required VSX Provisioning operations in the environment.

## Syntax

```
vsx_provisioning_tool -h

vsx_provisioning_tool [-s <Mgmt Server>] {-u <Username> | -c
<Certificate>} -p <Password>
    -o <Commands> [-a] -L
    -f <Input File> [-l <Line>] [-a] -L
```

## Parameters

| Parameter        | Description                                                                                                                                                                                                                                                                                                                          |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -h               | Shows the built-in usage.                                                                                                                                                                                                                                                                                                            |
| -s <Mgmt Server> | Specifies the Security Management Server or the applicable Domain Management Server.<br>Enter the IPv4 or IPv6 address, or the resolvable hostname name.<br>This parameter is mandatory when you run the tool: <ul style="list-style-type: none"> <li>■ From a SmartConsole computer</li> <li>■ On a Multi-Domain Server.</li> </ul> |
| -u <Username>    | Specifies the Management Server administrator's user name.                                                                                                                                                                                                                                                                           |
| -c <Certificate> | Specifies the path and the name for the Management Server administrator's certificate file.                                                                                                                                                                                                                                          |

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -p<br><Password>   | Specifies the password of the: <ul style="list-style-type: none"> <li>■ Management Server administrator</li> <li>■ Certificate file</li> </ul>                                                                                                                                                                                                                                                                   |
| -o<br><Commands>   | Executes the commands you enter on the command line.<br>See <a href="#">"vsx_provisioning_tool Commands" on page 2071</a> .                                                                                                                                                                                                                                                                                      |
| -f <Input<br>File> | Specifies the path and the name for the file with the commands to execute.<br>The tool treats all text begins with a hash sign (#) as a comment and ignores it.<br>This way you can add comments on separate lines, or in-line.<br>See: <ul style="list-style-type: none"> <li>■ <a href="#">"Transactions" on page 2070</a></li> <li>■ <a href="#">"vsx_provisioning_tool Commands" on page 2071</a></li> </ul> |
| -l <Line>          | Specifies the line number in <Input File>, from which to start to execute the commands.<br>You can use this "-l" parameter only together with the "-f" parameter.                                                                                                                                                                                                                                                |
| -a                 | Specifies that before the tool executes the specified commands, it must make sure it can connect to all VSX Gateways.<br> <b>Note</b> - This does not guarantee that a VSX Gateway can successfully apply all the specified commands.                                                                                         |
| -L                 | Specifies local authentication mode.                                                                                                                                                                                                                                                                                                                                                                             |

## Exit Codes

| Exit Code | Description                                                                                                                                                                                 |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0         | The tool successfully applied all changes, on all VSX Cluster Members.                                                                                                                      |
| 1         | The tool successfully applied all changes to the management database, but not to all VSX Cluster Members.                                                                                   |
| 2         | The tool successfully applied all changes, but SIC communication failed to establish with at least one VSX Cluster Member.                                                                  |
| 3         | Connectivity test failed with at least one VSX Cluster Member (if you used the "-a" parameter).<br>The tool did not apply changes to the management database, or to the VSX Cluster Member. |
| 4         | The tool failed to apply changes (due to internal error, syntax error, or another reason).                                                                                                  |

**Note** - If commands are executed from a file with multiple transactions, the exit code refers to the last transaction processed.

### Example 1

Run the tool on the Security Management Server.

Execute the commands from the text `/var/log/vsx.txt` file.

```
vsx_provisioning_tool -s localhost -u admin -p mypassword -f /var/log/vsx.txt
```

### Example 2

Run the tool on the Multi-Domain Server in the context of the Domain Management Server called `MyDomain`.

Create a new Virtual System object called `VS1` on the VSX Cluster object called `VSXCluster1`

In the new Virtual System object, on the interface `eth4`, add a VLAN interface with VLAN ID 100 and IPv4 address 1.1.1.1/24.

```
mdsensv MyDomain
vsx_provisioning_tool -s localhost -u admin -p mypassword -o add vd name VS1 vsx VSXCluster1, add interface name eth4.100 ip 1.1.1.1/24
```

# Transactions

## Notes:

- A transaction is a set of operations performed on one Virtual Device.
- The utility commits all operations to the management database together when the transaction ends.  
If the transaction fails, the utility discards all its commands.
- You must specify the name of the Virtual Device with a parameter in the first command.  
You do not need to specify this name again in other commands of the same transaction.
- You cannot send operations to different Virtual Devices in one transaction.
- You cannot start a new transaction until you exit the one before.
- When you send commands with the "-o" parameter, you can enter multiple commands (for example: add a Virtual System and then add interfaces and routes to it).  
Separate the commands with a comma ( , ).  
All the commands are one transaction.  
The "-o" parameter does not support explicit transaction commands.
- When you send commands with the "-f" parameter, you can use explicit transaction commands (see ["vsx\\_provisioning\\_tool Commands" on page 2071](#)).
- Commands from a file can be one or more transactions:
  - If not inside a transaction, the current line is one transaction, which the utility automatically commits.  
You can write multiple commands in one line (as one transaction), separated with a comma ( , ).
  - If currently inside a transaction, the utility processes the lines, but does not take action until the transaction ends.

## vsx\_provisioning\_tool Commands

All `vsx_provisioning_tool` commands are pairs of a key and a value.

The first two words in each command must appear in the correct order.

Other pairs can be written in any order.

## Explicit Transaction Commands

| Operation               | Command Syntax                  |
|-------------------------|---------------------------------|
| Begin a new transaction | <code>transaction begin</code>  |
| End a transaction       | <code>transaction end</code>    |
| Cancel a transaction    | <code>transaction cancel</code> |

 **Note** - SIC with the Virtual System is established automatically. If it fails, operations continue, and the transaction returns error code **2**.

## Adding a VSX Gateway

### Description

This command adds a new VSX Gateway object.

### Syntax

```
add vsx type gateway name <Name of VSX Gateway Object> version
<Version> main_ip <Main IPv4 Address> [main_ip6 <Main IPv6
Address>] sic_otp <Activation Key> [rule_snmp {enable | disable}]
[rule_ssh {enable | disable}] [rule_ping {enable | disable} [rule_
ping6 {enable | disable}] [rule_https {enable | disable}] [rule_
drop {enable | disable}]
```

**Note** - In this transaction, you can only add the "set physical interface" command.

### Parameters

| type                              | gateway             | You must use the value "gateway" to add a new VSX Gateway object.                                                                        |
|-----------------------------------|---------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| name <Name of VSX Gateway Object> | Object name         | Defines the name of the VSX Gateway object. You cannot use spaces or Check Point reserved words.                                         |
| version <Version>                 | Check Point version | Defines the Check Point version of the VSX Gateway object. You must enter the exact version as appears in SmartConsole (case-sensitive). |
| main_ip <Main IPv4 Address>       | IPv4 Address        | Defines the main IPv4 Address of the VSX Gateway object.                                                                                 |
| main_ip6 <Main IPv6 Address>      | IPv6 Address        | Defines the main IPv6 Address of the VSX Gateway object.                                                                                 |
| sic_otp <Activation Key>          | SIC password        | You must enter the same Activation Key you entered during the First Time Configuration Wizard of the VSX Gateway.                        |

| <pre>rule_snmp {enable   disable}</pre>  | <ul style="list-style-type: none"> <li>■ enable</li> <li>■ disable</li> </ul> | <p>Controls how to process all SNMP packets sent to the VSX Gateway:</p> <ul style="list-style-type: none"> <li>■ enable - Allows all SNMP packets</li> <li>■ disable - Drops all SNMP packets (default)</li> </ul>                                          |
|------------------------------------------|-------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>rule_ssh {enable   disable}</pre>   | <ul style="list-style-type: none"> <li>■ enable</li> <li>■ disable</li> </ul> | <p>Controls how to process all SSH packets sent to the VSX Gateway:</p> <ul style="list-style-type: none"> <li>■ enable - Allows all SSH packets</li> <li>■ disable - Drops all SSH packets (default)</li> </ul>                                             |
| <pre>rule_ping {enable   disable}</pre>  | <ul style="list-style-type: none"> <li>■ enable</li> <li>■ disable</li> </ul> | <p>Controls how to process all ICMP Echo Request (ping) packets sent to the VSX Gateway:</p> <ul style="list-style-type: none"> <li>■ enable - Allows all IPv4 ping packets</li> <li>■ disable - Drops all IPv4 ping packets (default)</li> </ul>            |
| <pre>rule_ping6 {enable   disable}</pre> | <ul style="list-style-type: none"> <li>■ enable</li> <li>■ disable</li> </ul> | <p>Controls how to process all ICMPv6 Echo Request (ping) packets sent to the VSX Gateway:</p> <ul style="list-style-type: none"> <li>■ enable - Allows all IPv6 ping packets</li> <li>■ disable - Drops all IPv6 ping packets (default)</li> </ul>          |
| <pre>rule_https {enable   disable}</pre> | <ul style="list-style-type: none"> <li>■ enable</li> <li>■ disable</li> </ul> | <p>Controls how to process all HTTPS packets sent to the VSX Gateway:</p> <ul style="list-style-type: none"> <li>■ enable - Allows all HTTPS packets</li> <li>■ disable - Drops all HTTPS packets (default)</li> </ul>                                       |
| <pre>rule_drop {enable   disable}</pre>  | <ul style="list-style-type: none"> <li>■ enable</li> <li>■ disable</li> </ul> | <p>Controls how to process all packets (other than SNMP, SSH, ICMP, ICMPv6, HTTPS) sent to the VSX Gateway:</p> <ul style="list-style-type: none"> <li>■ enable - Drops all other packets (default)</li> <li>■ disable - Allows all other packets</li> </ul> |

## Example

```
vsx_provisioning_tool -s localhost -u admin -p mypassword -o add vsx name VSX_GW1 type gateway main_ip 192.168.20.1 version R82.10 sic_otp ABCDEFG rule_ssh enable rule_ping enable
```

## Adding a VSX Cluster

### Description

This command adds a new VSX Cluster object.

### Syntax

```
add vsx type cluster name <Name of VSX Cluster Object> version
<Version> main_ip <Main Virtual IPv4 Address> main_ip6 <Main
Virtual IPv6 Address> cluster_type {vsls | ha | crbm} sync_if_name
<Name of Sync Interface> sync_netmask <Sync Interface Netmask>
[rule_snmp {enable | disable}] [rule_ssh {enable | disable}]
[rule_ping {enable | disable} [rule_ping6 {enable | disable}]
[rule_https {enable | disable}] [rule_drop {enable | disable}]
```

**Important** - You must run the "add vsx\_member" command for each VSX Cluster Member in the same transaction as the "add vsx type cluster name" command.

#### Syntax

```
add vsx_member name <Member Name> [main_ip <Member Main
IPv4 Address>] [main_ip6 <Member Main IPv6 Address>] sync_
ip <Sync Interface IPv4 Address> sic_otp <SIC Password>
```

### Parameters

| Parameter                           | Value               | Notes                                                                                                                                    |
|-------------------------------------|---------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| type                                | cluster             | You must use the value "cluster" to add a new VSX Cluster object.                                                                        |
| name <Name of VSX Cluster Object>   | Object name         | Defines the name of the VSX Cluster object. You cannot use spaces or Check Point reserved words.                                         |
| version <Version>                   | Check Point version | Defines the Check Point version of the VSX Cluster object. You must enter the exact version as appears in SmartConsole (case-sensitive). |
| main_ip <Main Virtual IPv4 Address> | IPv4 Address        | Defines the main IPv4 Virtual Address of the VSX Cluster object.                                                                         |

| Parameter                                                                                | Value                                                                                                   | Notes                                                                                                                                                                                                                                                                                          |
|------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>main_ip6</code> <Main Virtual IPv6 Address>                                        | IPv6 Address                                                                                            | Defines the main IPv6 Virtual Address of the VSX Cluster object.                                                                                                                                                                                                                               |
| <code>cluster_type</code><br>{ <code>vsls</code>   <code>ha</code>   <code>crbm</code> } | Cluster type                                                                                            | Defines the cluster type.<br>Enter one of these: <ul style="list-style-type: none"> <li>▪ <code>vsls</code> - Virtual System Load Sharing mode</li> <li>▪ <code>ha</code> - High Availability mode</li> <li>▪ <code>crbm</code> - X-Series appliances (former BlueCoat / Crossbeam)</li> </ul> |
| <code>sync_if_name</code><br><Name of Sync Interface>                                    | Sync interface name                                                                                     | Defines the name of the Cluster Synchronization interface.                                                                                                                                                                                                                                     |
| <code>sync_netmask</code><br><Sync Interface Netmask>                                    | IPv4 Network mask                                                                                       | Defines an IPv4 Netmask for the Cluster Synchronization interface (in a dot-quad format X.X.X.X).                                                                                                                                                                                              |
| <code>rule_snmp</code><br>{ <code>enable</code>   <code>disable</code> }                 | <ul style="list-style-type: none"> <li>▪ <code>enable</code></li> <li>▪ <code>disable</code></li> </ul> | Controls how to process all SNMP packets sent to the VSX Cluster Members: <ul style="list-style-type: none"> <li>▪ <code>enable</code> - Allows all SNMP packets</li> <li>▪ <code>disable</code> - Drops all SNMP packets (default)</li> </ul>                                                 |
| <code>rule_ssh</code><br>{ <code>enable</code>   <code>disable</code> }                  | <ul style="list-style-type: none"> <li>▪ <code>enable</code></li> <li>▪ <code>disable</code></li> </ul> | Controls how to process all SSH packets sent to the VSX Cluster Members: <ul style="list-style-type: none"> <li>▪ <code>enable</code> - Allows all SSH packets</li> <li>▪ <code>disable</code> - Drops all SSH packets (default)</li> </ul>                                                    |
| <code>rule_ping</code><br>{ <code>enable</code>   <code>disable</code> }                 | <ul style="list-style-type: none"> <li>▪ <code>enable</code></li> <li>▪ <code>disable</code></li> </ul> | Controls how to process all ICMP Echo Request (ping) packets sent to the VSX Cluster Members: <ul style="list-style-type: none"> <li>▪ <code>enable</code> - Allows all IPv4 ping packets</li> <li>▪ <code>disable</code> - Drops all IPv4 ping packets (default)</li> </ul>                   |

| Parameter                        | Value                                                                         | Notes                                                                                                                                                                                                                                                                |
|----------------------------------|-------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| rule_ping6<br>{enable   disable} | <ul style="list-style-type: none"> <li>■ enable</li> <li>■ disable</li> </ul> | <p>Controls how to process all ICMPv6 Echo Request (ping) packets sent to the VSX Cluster Members:</p> <ul style="list-style-type: none"> <li>■ enable - Allows all IPv6 ping packets</li> <li>■ disable - Drops all IPv6 ping packets (default)</li> </ul>          |
| rule_https<br>{enable   disable} | <ul style="list-style-type: none"> <li>■ enable</li> <li>■ disable</li> </ul> | <p>Controls how to process all HTTPS packets sent to the VSX Cluster Members:</p> <ul style="list-style-type: none"> <li>■ enable - Allows all HTTPS packets</li> <li>■ disable - Drops all HTTPS packets (default)</li> </ul>                                       |
| rule_drop<br>{enable   disable}  | <ul style="list-style-type: none"> <li>■ enable</li> <li>■ disable</li> </ul> | <p>Controls how to process all packets (other than SNMP, SSH, ICMP, ICMPv6, HTTPS) sent to the VSX Cluster Members:</p> <ul style="list-style-type: none"> <li>■ enable - Drops all other packets (default)</li> <li>■ disable - Allows all other packets</li> </ul> |

## Example

```
vsx_provisioning_tool -s localhost -u admin -p mypassword -o add vsx name VSX1 type cluster cluster_type vs1s main_ip 192.168.1.1 version R82.10 sync_if_name eth3 sync_netmask 255.255.255.0 rule_ssh enable rule_ping enable
```

## Adding a Virtual Device

### Description

This command adds a new Virtual Device object:

- Virtual System
- Virtual System in Bridge Mode
- Virtual Switch
- Virtual Router

### Syntax

```
add vd name <Name of Virtual Device Object> vsx <Name of VSX
Gateway or VSX Cluster Object > [type {vs | vsbm | vsw | vr}] [vs_
mtu <MTU>] [instances <Number of IPv4 CoreXL Firewall instances>]
[instances6 <Number of IPv6 CoreXL Firewall instances>] [main_ip
<Main IPv4 Address>] [main_ip6 <Main IPv6 Address>] [calc_topo_
auto {true | false}]
```

### Parameters

| Parameter                                        | Value                  | Notes                                                                                                                                                                                                                                    |
|--------------------------------------------------|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| name <Name of Virtual Device Object>             | Object name            | Defines the name of the Virtual Device object.<br>Mandatory parameter, if this is the first command in a transaction.                                                                                                                    |
| vsx <Name of VSX Gateway or VSX Cluster Object > | Parent object name     | Defines the name of the applicable VSX Gateway or VSX Cluster object, in which you create this Virtual Device.<br>You cannot use spaces or Check Point reserved words.<br>Mandatory parameter.                                           |
| type {vs   vsbm   vsw   vr}                      | Type of Virtual Device | Defines the type of the Virtual Device: <ul style="list-style-type: none"> <li>■ vs - Virtual System (default)</li> <li>■ vsbm - Virtual System in Bridge Mode</li> <li>■ vsw - Virtual Switch</li> <li>■ vr - Virtual Router</li> </ul> |

| Parameter                                                                | Value   | Notes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------------------------------------------------------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>vs_mtu &lt;MTU&gt;</code>                                          | Integer | <p>Defines the Global MTU value for all interfaces.</p> <p>This parameter is applicable only for a:</p> <ul style="list-style-type: none"> <li>Virtual System in Bridge Mode (type vsbm)</li> <li>Virtual Switch (type vsw)</li> </ul> <p>Default is 1500 bytes.</p> <p> <b>Note</b> - For a Virtual Switch, if you do not add a VLAN or physical interface in the same transaction, the utility ignores this value.</p> |
| <code>instances &lt;Number of IPv4 CoreXL Firewall instances&gt;</code>  | Integer | <p>Defines the number of IPv4 CoreXL Firewall instances.</p> <p>This parameter is applicable only for a:</p> <ul style="list-style-type: none"> <li>Virtual System (type vs)</li> <li>Virtual System in Bridge Mode (type vsbm)</li> </ul> <p>Default is 1.</p> <p>For more information about CoreXL, see <a href="#">R82.10 Performance Tuning Administration Guide</a>.</p>                                                                                                                             |
| <code>instances6 &lt;Number of IPv6 CoreXL Firewall instances&gt;</code> | Integer | <p>Defines the number of IPv6 CoreXL Firewall instances.</p> <p>This parameter is applicable only for a:</p> <ul style="list-style-type: none"> <li>Virtual System (type vs)</li> <li>Virtual System in Bridge Mode (type vsbm)</li> </ul> <p>Default is 1.</p> <p>For more information about CoreXL, see <a href="#">R82.10 Performance Tuning Administration Guide</a>.</p>                                                                                                                             |

| Parameter                                       | Value                                                                 | Notes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------------------------------|-----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>main_ip &lt;Main IPv4 Address&gt;</code>  | IPv4 Address                                                          | <p>Defines the main IPv4 Address of the Virtual Device object.</p> <p>This parameter is applicable only for a:</p> <ul style="list-style-type: none"> <li>Virtual System (<code>type vs</code>)</li> <li>Virtual Router (<code>type vr</code>)</li> </ul> <p> <b>Note</b> - If you do not specify this value explicitly, the utility uses the IPv4 address of the first interface added to the new device.</p>       |
| <code>main_ip6 &lt;Main IPv6 Address&gt;</code> | IPv6 Address                                                          | <p>Defines the main IPv6 Address of the Virtual Device object.</p> <p>This parameter is applicable only for a:</p> <ul style="list-style-type: none"> <li>Virtual System (<code>type vs</code>)</li> <li>Virtual Router (<code>type vr</code>)</li> </ul> <p> <b>Note</b> - If you do not specify this value explicitly, the utility uses the IPv6 address of the first interface added to the new device.</p>       |
| <code>calc_topo_auto {true   false}</code>      | <ul style="list-style-type: none"> <li>true</li> <li>false</li> </ul> | <p>Defines how to calculate topology based on routes:</p> <ul style="list-style-type: none"> <li><code>true</code> - Automatically calculate topology based on routes (default)</li> <li><code>false</code> - Does not calculate topology based on routes (administrator can configure it manually)</li> </ul> <p>This parameter is applicable only for a:</p> <ul style="list-style-type: none"> <li>Virtual System (<code>type vs</code>)</li> <li>Virtual Router (<code>type vr</code>)</li> </ul> |

### Example - Adding a Virtual Switch "VirtSwitch1" to the VSX Gateway "VSX\_GW1"

```
vsx_provisioning_tool -s localhost -u admin -p mypassword -o add vd name VirtSwitch1 vsx VSX_GW1 type vsw
```

## Deleting a Virtual Device

### Description

This command deletes a Virtual Device object:

- Virtual System
- Virtual System in Bridge Mode
- Virtual Switch
- Virtual Router

You cannot delete a Virtual Device if:

- It is referenced by a policy rule.
- It is referenced by other objects.
- It is enabled for global use in a Multi-Domain Security Management environment.

**Important** - After you delete a Virtual Device, you cannot have more commands in the same transaction.

### Syntax

```
remove vd name <Name of Virtual Device Object>
```

### Parameters

| Parameter                                               | Value       | Notes                                                                                                                   |
|---------------------------------------------------------|-------------|-------------------------------------------------------------------------------------------------------------------------|
| <code>name &lt;Name of Virtual Device Object&gt;</code> | Object name | Specifies the name of the Virtual Device object.<br>Mandatory parameter, if this is the first command in a transaction. |

### Example

```
vsx_provisioning_tool -s localhost -u admin -p mypassword -o remove vd name VirtSwitch1
```

## Modifying Settings of a Virtual Device

### Description

This command changes the settings of an existing Virtual Device object:

- Virtual System
- Virtual System in Bridge Mode
- Virtual Switch
- Virtual Router

### Syntax

```
set vd name <Name of Virtual Device Object> [vs_mtu <MTU>]
[instances <Number of IPv4 CoreXL Firewall instances>] [instances6
<Number of IPv6 CoreXL Firewall instances>] [main_ip <Main IPv4
Address>] [main_ip6 <Main IPv6 Address>] [calc_topo_auto {true |
false}]
```

### Parameters

| Parameter                            | Value       | Notes                                                                                                                                                                                                                             |
|--------------------------------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| name <Name of Virtual Device Object> | Object name | Specifies the name of the Virtual Device object.<br>Mandatory parameter, if this is the first command in a transaction.                                                                                                           |
| vs_mtu <MTU>                         | Integer     | Specifies the Global MTU value for all interfaces.<br>This parameter is applicable only for a: <ul style="list-style-type: none"> <li>▪ Virtual System in Bridge Mode</li> <li>▪ Virtual Switch</li> </ul> Default is 1500 bytes. |

| Parameter                                                          | Value        | Notes                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------------------------------------------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>instances</code> <Number of IPv4 CoreXL Firewall instances>  | Integer      | <p>Specifies the number of IPv4 CoreXL Firewall instances.</p> <p>This parameter is applicable only for a:</p> <ul style="list-style-type: none"> <li>Virtual System</li> <li>Virtual System in Bridge Mode</li> </ul> <p>Default is 1.</p> <p>For more information about CoreXL, see <a href="#">R82.10 Performance Tuning Administration Guide</a>.</p>                                                                                    |
| <code>instances6</code> <Number of IPv6 CoreXL Firewall instances> | Integer      | <p>Specifies the number of IPv6 CoreXL Firewall instances.</p> <p>This parameter is applicable only for a:</p> <ul style="list-style-type: none"> <li>Virtual System</li> <li>Virtual System in Bridge Mode</li> </ul> <p>Default is 1.</p> <p>For more information about CoreXL, see <a href="#">R82.10 Performance Tuning Administration Guide</a>.</p>                                                                                    |

For example: <code>set vd name VS1 main_ip6 empty</code></p>  |

| Parameter                                  | Value                                                                                               | Notes                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------------------------|-----------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>calc_topo_auto {true   false}</code> | <ul style="list-style-type: none"> <li>■ <code>true</code></li> <li>■ <code>false</code></li> </ul> | <p>Specifies how to calculate topology based on routes:</p> <ul style="list-style-type: none"> <li>■ <code>true</code> - Automatically calculate topology based on routes (default)</li> <li>■ <code>false</code> - Does not calculate topology based on routes (administrator can configure it manually)</li> </ul> <p>This parameter is applicable only for a:</p> <ul style="list-style-type: none"> <li>■ Virtual System</li> <li>■ Virtual Router</li> </ul> |

## Example

```
vsx_provisioning_tool -s localhost -u admin -p mypassword -o set vd name VS1 instances 8 main_ip 192.0.2.6 calc_topo_auto false
```

## Adding an Interface to a Virtual Device

### Description

This command adds an interface to an existing Virtual Device object:

- Virtual System
- Virtual System in Bridge Mode
- Virtual Switch
- Virtual Router

### Syntax

```
add interface vd <Name of Virtual Device Object> {name <Name of
Interface> | leads_to <Name of VSW or VR Object>} ip <IPv4
Address>{/<IPv4 Prefix Length> | netmask <IPv4 Netmask> | prefix
<IPv4 Prefix>} ip6 <IPv6 Address>{/<IPv6 Prefix Length> | netmask6
<IPv6 Netmask> | prefix6 <IPv6 Prefix>} [propagate {true | false}]
[propagate6 {true | false}] [topology {external | internal_
undefined | internal_this_network | internal_specific [specific_
group <Name of Network Group Object>]]] [mtu <MTU>]
```

### Parameters

| Parameter                           | Value          | Notes                                                                                                                                                                                                                                                                                                                            |
|-------------------------------------|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| vd <Name of Virtual Device Object>  | Object name    | Specifies the name of the Virtual Device object. Mandatory parameter, if this is the first command in a transaction.                                                                                                                                                                                                             |
| name <Name of Interface>            | Interface name | Specifies the name of the physical or VLAN interface.<br> <b>Note</b> - You must use the "name" or "leads_to" parameter, but not both.                                                                                                        |
| leads_to <Name of VSW or VR Object> | Object name    | Specifies the name of the Virtual Switch or Virtual Router object, to which this interface connects. This parameter is applicable only for a Virtual System.<br> <b>Note</b> - You must use the "name" or "leads_to" parameter, but not both. |

| Parameter                                                                                                                  | Value              | Notes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Parameter                                                                     | Value                        | Notes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------------------------------------------------------------|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>specific_group</code><br><code>&lt;Network Group Object Name&gt;</code> | Name of Network Group Object | <p>If you specified the "topology internal_specific" parameter, then specify the name of the Network Group object that contains the applicable Network objects.</p> <p> <b>Note</b> - This parameter is applicable only if you disable the automatic topology calculation with the "set vd ... calc_topo_auto false" command (see <a href="#">"Modifying Settings of a Virtual Device" on page 2083</a>).</p> |
| <code>mtu &lt;MTU&gt;</code>                                                  | Integer                      | <p>Specifies the MTU value for this interface. Default is 1500 bytes.</p> <p>This parameter is applicable only for a:</p> <ul style="list-style-type: none"> <li>Virtual System</li> <li>Virtual Router</li> </ul>                                                                                                                                                                                                                                                                             |

### Example - Add VLAN interface eth4.100 with IPv4 1.1.1.1/24 to the Virtual System 'VirtSystem1'

```
vsx_provisioning_tool -s localhost -u admin -p mypassword -o add interface vd VirtSystem1 name eth4.100 ip 1.1.1.1/24
```

## Adding a Bridge Interface to a Virtual System

### Description

Some Software Blades and features are not supported on a Virtual System in Bridge Mode, because it may not have an IP address.

For example: Threat Emulation, Identity Awareness, Identity Awareness Captive Portal, and UserCheck Portal are not supported.

This command adds a Bridge interface to an existing regular Virtual System object that always has an IP address.

As a result, the Virtual System can support these Software Blades and features for the traffic that passes over the configured bridge interface.

### Notes:

- Names of bridge interfaces have a template "brX", where "X" is a digit.
- It is necessary to add subordinate interfaces in pairs to a bridge interface.
- To see the bridge interfaces you configured in the Virtual System object:
  1. Connect to the command line on the VSX Gateway (each VSX Cluster Member).
  2. Log in to the Expert mode.
  3. Go to the context of the Virtual System:

```
vsenv <VSID>
```

4. Examine the list of interfaces:

```
ifconfig
```

- You can delete bridge interfaces from a Virtual System either in SmartConsole, or with the "vsx\_provisioning\_tool" command (see ["Removing an Interface from a Virtual Device" on page 2094](#)).

### Syntax

```
attach bridge vd <Name of Virtual System Object> ifs1 <Name of  
First Subordinate Interface> ifs2 <Name of Second Subordinate  
Interface>
```

## Parameters

| Parameter                                                     | Value          | Notes                                                                                                                                                                                                                                                             |
|---------------------------------------------------------------|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>vd &lt;Name of Virtual System Object&gt;</code>         | Object name    | Specifies the name of the Virtual System object.<br>Mandatory parameter, if this is the first command in a transaction.                                                                                                                                           |
| <code>ifs1 &lt;Name of First Subordinate Interface&gt;</code> | Interface name | Specifies the name of the physical interface to be the first subordinate interface of a bridge interface.<br> <b>Note</b> - This physical interface must not have an IP address  |
| <code>ifs2 &lt;Name of First Second Interface&gt;</code>      | Interface name | Specifies the name of the physical interface to be the second subordinate interface of a bridge interface.<br> <b>Note</b> - This physical interface must not have an IP address |

### Example 1 - Adding a Bridge interface with subordinate interfaces "eth2" and "eth3" in the Virtual System "VS1"

```
vsx_provisioning_tool -s localhost -u admin -p mypassword -o attach bridge vd VS1 ifs1 eth2 ifs2 eth3
```

### Example 2 - Adding a Multi Bridge interface in the Virtual System "VS1"

In this example, we add pairs of VLAN interfaces to the Virtual System "VS1" to add a Multi Bridge interface (for more information, see the [R82.10 VSX Administration Guide](#) > section "Virtual System in Bridge Mode"):

- VLANs eth2.403 and eth3.403 as the first bridge interface
- VLANs eth2.504 and eth3.504 as the second bridge interface

The prerequisite is to configure both physical interfaces "eth2" and "eth3" as VLAN Trunks (see "[Configuring a Physical Interface as VLAN Trunk](#)" on page 2100).

```
vsx_provisioning_tool -s localhost -u admin -p mypassword -o attach bridge vd VS1 ifs1 eth2.403 ifs2 eth3.403, attach bridge ifs1 eth2.504 ifs2 eth3.504
```

## Adding a VPN Tunnel Interface to a Virtual Device

### Description

Virtual Tunnel Interface (VTI) is a virtual interface that is used for establishing a Route-Based VPN tunnel.

This command adds a VTI to an existing Virtual System object.

The VPN tunnel and its properties are defined by the VPN community that contains the two Security Gateways.

You must define the VPN community and its member Security Gateways before you can create a VTI.

To learn more about Route Based VPN, see the [R82.10 Site to Site VPN Administration Guide](#) > Chapter *Route Based VPN*.

### Syntax

```
add interface vd <Name of Virtual System Object> vpn_tunnel
numbered peer <Name of VPN Peer Object> local <Tunnel Local IP>
remote <Tunnel Remote IP> [tunnel_id <Tunnel ID>]
```

### Parameters

| Parameter                          | Value                                                                     | Notes                                                                                                                                                   |
|------------------------------------|---------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| vd <Name of Virtual System Object> | Object name                                                               | Specifies the name of the Virtual System object (as configured in SmartConsole).<br>Mandatory parameter, if this is the first command in a transaction. |
| vpn_tunnel numbered                | <ul style="list-style-type: none"> <li>■ true</li> <li>■ false</li> </ul> | Specifies the type of the VPN tunnel as numbered.<br>Uses a specified, static IPv4 addresses for local and remote connections.                          |
| peer <Name of VPN Peer Object>     | Object name                                                               | Specifies the name of the remote peer object as defined in the VPN community in SmartConsole.                                                           |

| Parameter                                                                  | Value              | Notes                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------------------------------------------------------------|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>local &lt;Tunnel Local IP&gt; remote &lt;Tunnel Remote IP&gt;</code> | IPv4 configuration | <p>Specifies the IPv4 addresses in dotted decimal format for the VPN tunnel endpoints:</p> <ul style="list-style-type: none"> <li>▪ <code>local &lt;Tunnel Local IP&gt;</code> - IPv4 address of the VPN tunnel on this Virtual System</li> <li>▪ <code>remote &lt;Tunnel Remote IP&gt;</code> - IPv4 address of the VPN tunnel on the remote VPN peer</li> </ul> <p>Applies to the Numbered VTI only.</p> |
| <code>tunnel_id &lt;Tunnel ID&gt;</code>                                   | Integer            | <p>Specifies the unique Tunnel ID (integer from 1 to 32768).</p> <p> <b>Note</b> - If the specified ID is already used by another VPN tunnel on this VSX Gateway or VSX Cluster Member, this parameter is ignored and the next available ID is used instead.</p>                                                          |

### Example - Numbered VTI

```
vsx_provisioning_tool -o add interface vd vs1 vpn_tunnel numbered peer AWS_Peer local 169.254.46.238 remote 169.254.46.237 tunnel_id 10
```

**Note** - Unnumbered VTIs are not supported.

## Removing an Interface from a Virtual Device

### Description

This command removes an interface from an existing Virtual Device object:

- Virtual System
- Virtual System in Bridge Mode
- Virtual Switch
- Virtual Router

#### Important:

- If the interface you remove leads to a Virtual Router, all routes through that interface are removed automatically.
- You must remove **all** subordinate interfaces of a bridge interface in the same transaction. This also removes the bridge interface.

**Note** - If there are routes that have a next-hop IP address, which would become inaccessible without this interface, the transaction fails.

### Syntax

```
remove interface vd <Name of Virtual Device Object> {name <Name of Interface> | leads_to <Name of VSW or VR Object>}
```

## Parameters

| Parameter                                              | Value          | Notes                                                                                                                                                                                                                                                                                                                          |
|--------------------------------------------------------|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>vd &lt;Name of Virtual Device Object&gt;</code>  | Object name    | Specifies the name of the Virtual Device object. Mandatory parameter, if this is the first command in a transaction.                                                                                                                                                                                                           |
| <code>name &lt;&lt;Name of Interface&gt;&gt;</code>    | Interface name | Specifies the name of the physical or VLAN interface.<br> <b>Note</b> - You must use the "name" or "leads_to" parameter, but not both.                                                                                                        |
| <code>leads_to &lt;Name of VSW or VR Object&gt;</code> | Object name    | Specifies the name of the Virtual Switch or Virtual Router object, to which this interface connects. This parameter is applicable only for a Virtual System.<br> <b>Note</b> - You must use the "name" or "leads_to" parameter, but not both. |

### Example 1 - Removing a VLAN interface from a Virtual System "VS1"

```
vsx_provisioning_tool -s localhost -u admin -p mypassword -o remove interface vd VS1 name eth4.100
```

### Example 2 - Removing all subordinate interfaces "eth2" and "eth3" of a bridge interface in the Virtual System "VS1"

```
vsx_provisioning_tool -s localhost -u admin -p mypassword -o remove interface vd VS1 name eth2, remove interface vd VS1 name eth3
```

# Modifying Settings of an Interface

## Description

This command changes the settings of an interface that belongs to an existing Virtual Device object:

- Virtual System
- Virtual System in Bridge Mode
- Virtual Switch
- Virtual Router

 **Note** - You cannot change or remove the IP address or netmask of an existing interface with this command. You can remove the interface and add a new interface with a different IP address, but not all the previous interface settings are kept.

## Syntax

```
set interface vd <Name of Virtual Device Object> {name <Name of Interface> [new_name <Name of New Interface>] | leads_to <Name of VSW or VR Object> [new_leads_to <Name of New VSW or VR Object>]} [propagate {true | false}] [propagate6 {true | false}] [topology {external | internal_undefined | internal_this_network | internal_specific [specific_group <Network Group Object Name>]]] [mtu <MTU>]
```

## Parameters

| Parameter                          | Value          | Notes                                                                                                                                                                                                                     |
|------------------------------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| vd <Name of Virtual Device Object> | Object name    | Specifies the name of the Virtual Device object.<br>Mandatory parameter, if this is the first command in a transaction.                                                                                                   |
| name <Name of Interface>           | Interface name | Specifies the name of the physical or VLAN interface.<br> <b>Note</b> - You must use the "name" or "leads_to" parameter, but not both. |

| Parameter                                                | Value                                                                     | Notes                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------------------------------------|---------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>new_name</code> <Name of New Interface>            | Interface name                                                            | <p>You can change the name, but not the type of interface.</p> <p> <b>Note</b> - You can change a VLAN or physical interface only to a VLAN or physical interface.</p>                                                                                                                                                                                                      |
| <code>leads_to</code> <Name of VSW or VR Object>         | Object name                                                               | <p>Specifies the name of the Virtual Switch or Virtual Router object, to which this interface connects. This parameter is applicable only for a Virtual System.</p> <p> <b>Note</b> - You must use the "name" or "leads_to" parameter, but not both.</p>                                                                                                                    |
| <code>new_leads_to</code> <Name of New VSW or VR Object> | Object name                                                               | <p>You can where the interface leads:</p> <ul style="list-style-type: none"> <li>■ You can change an interface that leads to a Virtual Switch only to lead to a different Virtual Switch.</li> <li>■ You can change an interface that leads to a Virtual Router only to lead to a different Virtual Router.</li> </ul>                                                                                                                                       |
| <code>propagate</code> {true   false}                    | <ul style="list-style-type: none"> <li>■ true</li> <li>■ false</li> </ul> | <p>Controls how to propagate the IPv4 routes to adjacent Virtual Devices:</p> <ul style="list-style-type: none"> <li>■ <code>true</code> - Propagate the IPv4 routes</li> <li>■ <code>false</code> - Do not propagate the IPv4 routes (default)</li> </ul> <p> <b>Note</b> - This parameter is applicable only for a Virtual System with VLAN or physical interfaces.</p> |

|-----------------------------------------------|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| specific_group<br><Network Group Object Name> | Name of Network Group Object | <p>If you specified the "topology internal_specific" parameter, then specify the name of the Network Group object that contains the applicable Network objects.</p> <p> <b>Note</b> - This parameter is applicable only if you disable the automatic topology calculation with the "set vd ... calc_topo_auto false" command (see <a href="#">"Modifying Settings of a Virtual Device" on page 2083</a>).</p> |
| mtu <MTU>                                     | Integer                      | <p>Specifies the MTU value for this interface.</p> <p>Default is 1500 bytes.</p> <p>This parameter is applicable only for:</p> <ul style="list-style-type: none"> <li>Virtual System</li> <li>Virtual Router</li> </ul>                                                                                                                                                                                                                                                                        |

**Example - On the Virtual System "VS1", change the VLAN interface eth4.10 to the physical interface eth5**

```
vsx_provisioning_tool -s localhost -u admin -p mypassword -o set interface vd VS1 name eth4.100 new_name eth5 propagate true topology internal_specific specific_group NYGWS
```

## Configuring a Physical Interface as VLAN Trunk

### Description

This command configures a physical interface as VLAN Trunk.

This is required to configure VLAN interfaces the physical interface.

**Important** - Make sure the physical interface you configure as VLAN Trunk does not have an IP address.

### Syntax

```
set physical_interface vd <Name of VSX Gateway or VSX Cluster Object> name <Name of Interface> vlan_trunk {true | false}
```

### Parameters

| Parameter                                                         | Value                                                                     | Notes                                                                                                                                                                                             |
|-------------------------------------------------------------------|---------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>vd &lt;Name of VSX Gateway or VSX Cluster Object&gt;</code> | Object name                                                               | Specifies the name of the VSX Gateway or VSX Cluster object. Mandatory parameter, if this is the first command in a transaction.                                                                  |
| <code>name &lt;Name of Interface&gt;</code>                       | Interface name                                                            | Specifies the name of the physical interface.                                                                                                                                                     |
| <code>vlan_trunk {true   false}</code>                            | <ul style="list-style-type: none"> <li>■ true</li> <li>■ false</li> </ul> | Controls whether this physical interface is a VLAN Trunk: <ul style="list-style-type: none"> <li>■ true - VLAN Trunk interface</li> <li>■ false - Regular physical interface (default)</li> </ul> |

### Example - On the VSX Gateway "VSX1" configure the physical interface eth2 as VLAN Trunk

```
vsx_provisioning_tool -s localhost -u admin -p mypassword -o set physical_interface vd VSX1 name eth2 vlan_trunk true
```

## Adding a Route

### Description

This command adds an IPv4 or IPv6 route to an existing Virtual System or Virtual Router object.

**Note** - This command detects IPv4 and IPv6 automatically.

### Syntax

```
add route vd <Name of VS or VR Object> destination {<IP Address>
[/<IP Prefix>] | default | default6} [{netmask <IP Netmask> |
prefix <IP Prefix>}] {next_hop <Next Hop IP Address> | leads_to
<Name of VS or VR Object>} [propagate {true | false}]
```

### Parameters

| Parameter                                                      | Value                                    | Notes                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------------------------------------------------|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| vd <Name of VS or VR Object>                                   | Object name                              | Specifies the name of the Virtual System or Virtual Router object.<br>Mandatory parameter, if this is the first command in a transaction.                                                                                                                                                                                                                                                                         |

| Parameter                                                       | Value                                                                     | Notes                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------------------------------------------------|---------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>next_hop</code><br><i>&lt;Next Hop IP Address&gt;</i>     | IP Address                                                                | Specifies the IP address of the next hop of the route.<br> <b>Notes:</b> <ul style="list-style-type: none"> <li>■ This IP address must be on a subnet of an existing interface.</li> <li>■ You must use the "next_hop" or "leads_to" parameter, but not both.</li> </ul>                                                    |
| <code>leads_to</code><br><i>&lt;Name of VS or VR Object&gt;</i> | Object name                                                               | Specifies the name of the Virtual System or Virtual Router object, which is the next hop for the configured route.<br> <b>Note</b> - You must use the "next_hop" or "leads_to" parameter, but not both.                                                                                                                     |
| <code>propagate</code><br><code>{true   false}</code>           | <ul style="list-style-type: none"> <li>■ true</li> <li>■ false</li> </ul> | Controls how to propagate the IP routes to adjacent Virtual Devices: <ul style="list-style-type: none"> <li>■ true - Propagate the IP routes</li> <li>■ false - Do not propagate the IP routes (default)</li> </ul>  <b>Note</b> - The "propagate" parameter is applicable only if you specified the "next_hop" parameter. |

**Example - Adding a route on the Virtual System "VS1" that uses the default IPv4 route as a destination and the Virtual Router "VR3" as a next hop**

```
vsx_provisioning_tool -s localhost -u admin -p mypassword -o add route vd VS1 destination default leads_to VR3
```

## Removing a Route

### Description

This command removes an IPv4 or IPv6 route from an existing Virtual System or Virtual Router object.

**Note** - This command detects IPv4 and IPv6 automatically.

### Syntax

```
remove route vd <Name of VS or VR Object> destination {<IP
Address>[/<IP Prefix>] | default | default6} [{netmask <IP
Netmask> | prefix <IP Prefix>}]
```

### Parameters

| Parameter                                                     | Value                                    | Notes                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------------------------------------------|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**Example - Removing a route from the Virtual System "VS1" that uses the default IPv6 route as a destination**

```
vsx_provisioning_tool -s localhost -u admin -p mypassword -o remove route vd VS1 destination default6
```

# Showing Virtual Device Data

## Description

This command shows the information about an existing Virtual Device object.

## Syntax

```
show vd name <Name of Virtual Device Object>
```

## Parameters

| Parameter                                             | Value                      | Notes                                                                    |
|-------------------------------------------------------|----------------------------|--------------------------------------------------------------------------|
| <code>vd &lt;Name of Virtual Device Object&gt;</code> | Name of the Virtual Device | Specifies the name of the Virtual Device object.<br>Mandatory parameter. |

## Comments

- The command shows only non-automatic routes.
- The command does not show routes that are created automatically with route propagation.
- For a Virtual Router and Virtual Switch:  
The command does not show the `wrpj` interfaces (created automatically) that connect to Virtual Systems.

## Script Examples

**Note** - Line numbers in the left column are written only to make it easier to read the script examples.

### Example 1

Create a Virtual System connected to a Virtual Router.

Add a default route on the Virtual System that routes the traffic to the Virtual Router.

Add applicable routes on the Virtual Router to route the traffic to the Virtual System.

| Line | Command                                                       |
|------|---------------------------------------------------------------|
| 1    | transaction begin                                             |
| 2    | add vd name VR1 vsx VSX1 type vr                              |
| 3    | add interface name eth3.100 ip 10.0.0.1/24                    |
| 4    | transaction end                                               |
| 5    | transaction begin                                             |
| 6    | add vd name VR2 vsx VSX2 type vr                              |
| 7    | add interface name eth3.200 ip 20.0.0.1/24                    |
| 8    | transaction end                                               |
| 9    | transaction begin                                             |
| 10   | add vd name VS1 vsx VSX1                                      |
| 11   | add interface leads_to VR1 ip 192.168.1.1/32                  |
| 12   | add interface name eth4.20 ip 192.168.20.1/24 propagate true  |
| 13   | add route destination default leads_to VR1                    |
| 14   | add route destination 192.168.40.0/25 next_hop 192.168.20.254 |
| 15   | transaction end                                               |

## Example 2

Create a Virtual System connected to a Virtual Switch, with manual topology.

| Line | Command                                                                                        |
|------|------------------------------------------------------------------------------------------------|
| 1    | transaction begin                                                                              |
| 2    | add vd name VSW1 vsx VSX1 type vsw vs_mtu 1400                                                 |
| 3    | add interface name eth3.100                                                                    |
| 4    | transaction end                                                                                |
| 5    | transaction begin                                                                              |
| 6    | add vd name VS1 vsx VSX1 calc_topo_auto false                                                  |
| 7    | add interface leads_to VSW1 ip 10.0.0.1/24 ip6 2001::1/64<br>topology external                 |
| 8    | add interface name eth4.20 ip 192.168.20.1/25 ip6<br>2020::1/64 topology internal_this_network |
| 9    | add route destination default next_hop 10.0.0.254                                              |
| 10   | add route destination default6 next_hop 2001::254                                              |
| 11   | transaction end                                                                                |

## Example 3

Add CoreXL Firewall instances to the Virtual System made in the last example.

Turn on automatic calculation of topology.

Change the name of the internal interface, and decrease its MTU.

| Line | Command                                                                   |
|------|---------------------------------------------------------------------------|
| 1    | <code>transaction begin</code>                                            |
| 2    | <code>set vd name VS1 instances 4 instances6 2 calc_topo_auto true</code> |
| 3    | <code>set interface name eth4.20 new_name eth4.21 mtu 1400</code>         |
| 4    | <code>transaction end</code>                                              |

# QoS Commands

For more information about QoS, see the [R82.10 QoS Administration Guide](#).

# etmstart

## Description

Starts the QoS Software Blade on the Security Gateway - starts the QoS daemon `fgd50`, and fetches the QoS policy from the Management Servers configured in the `$FWDIR/conf/masters` file on the Security Gateway.

For more information, see:

- [R82.10 QoS Administration Guide](#)
- [sk41585: How to control and debug QoS \(FloodGate-1\)](#)

## Syntax

```
etmstart
```

**Important** - On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

## Example

```
[Expert@MyGW:0]# etmstart
QoS: Starting fgd50

QoS: Fetching QoS Policy from masters
Fetching QoS Software Blade Policy:
  Received Policy. Downloading...

eth0(inbound), eth0(outbound).
Download OK.
Done.
QoS started
[Expert@MyGW:0]#
```

# etmstop

## Description

Stops the QoS Software Blade on the Security Gateway - kills the QoS daemon `fgd50` and then unloads the QoS policy.

For more information, see:

- [R82.10 QoS Administration Guide](#)
- [sk41585: How to control and debug FloodGate-1 \(QoS\)](#)

## Syntax

```
etmstop
```

**Important** - On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

## Example

```
[Expert@CXLI_192.168.3.52:0]# etmstop
Unloading QoS Policy:
Target(s): CXLI_192.168.3.52
  CXLI_192.168.3.52: QoS policy unloaded successfully.
Done.
QoS stopped
[Expert@CXLI_192.168.3.52:0]#
```

# fgate

This section describes:

## The 'fgate' command on Management Server

### Description

Installs and uninstalls the QoS policy on the managed Security Gateways.

Shows the status of the QoS Software Blade on the managed Security Gateways.

For more information, see:

- [R82.10 QoS Administration Guide](#)
- [sk41585: How to control and debug FloodGate-1 \(QoS\)](#)

### Syntax

```
fgate [-d]
      load <Name of QoS Policy>.F <GW1> <GW2> ... <GWN>
      stat
      -h
      <GW1> <GW2> ... <GWN>
      unload <GW1> <GW2> ... <GWN>
      ver
```

### Parameters

| Parameter | Description                                                                                                                                                                                                                                                                                                                                               |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d        | <p>Runs the command in debug mode.</p> <p>Use only if you troubleshoot the command itself.</p> <p> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p> |

| Parameter                                                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Examples

### Example 1 - Installing the QoS policy on one Security Gateway specified by its IP address

```
[Expert@MGMT:0]# fgate load MyPolicy.F 192.168.3.52
QoS rules verified OK!
Downloading QoS Policy: MyPolicy.F...
Target(s): MyGW
  MyGW: QoS policy transferred to module: MyGW.
  MyGW: QoS policy installed successfully.
Done.
[Expert@MGMT:0]#
```

### Example 2 - Installing the QoS policy on two cluster members specified by their object names

```
[Expert@MGMT:0]# fgate load MyPolicy.F MyClusterMember1 MyClusterMember2
QoS rules verified OK!
Downloading QoS Policy: MyPolicy.F...
  MyClusterMember1: QoS policy transferred to module: MyClusterMember1.
  MyClusterMember1: QoS policy installed successfully.
  MyClusterMember2: QoS policy transferred to module: MyClusterMember2.
  MyClusterMember2: QoS policy installed successfully.
Done.
[Expert@MGMT:0]#
```

### Example 3 - Viewing the QoS status on one Security Gateway specified by its object name

```
[Expert@MGMT:0]# fgate stat MyGW

Module name: MyGW
=====

Product: QoS Software Blade
Version: R82.10
Kernel Build: 456
Policy Name: MyPolicy
Install time: Wed Dec 4 19:53:48 2019
Interfaces Num: 1

Interface table
-----
|Name|Dir|Limit (Bps)|Avg Rate (Bps)|Conns|Pend pkts|Pend bytes|
-----
|eth0|in | 1250000000|          0|    0|        0|         0|
|eth0|out| 1250000000|          0|    0|        0|         0|
-----

[Expert@MGMT:0]#
```

### Example 4 - Viewing the QoS Software Blade version

```
[Expert@MGMT:0]# fgate ver
This is Check Point QoS Software Blade R82.10 - Build 123
[Expert@MGMT:0]#
```

## The 'fgate' command on Security Gateway

### Description

Installs and uninstalls the QoS policy on the managed Security Gateways.

Shows the status of the QoS Software Blade on the managed Security Gateways.

Controls the QoS debug.

For more information, see:

- [R82.10 QoS Administration Guide](#)
- [sk41585: How to control and debug FloodGate-1 \(QoS\)](#)

### Syntax

```
fgate [-d]
      ctl
          -h
          <QoS Module> {on | off}
      debug
          on
          off
      fetch
          -f
          <Management Server>
      kill [-t <Signal Number>] <Name of QoS Process>
      load
      log
          on
          off
          stat
      stat [-h]
      ver [-k]
      unload
```

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

## Parameters

| Parameter                                      | Description                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-d</code>                                | <p>Runs the command in debug mode.<br/>Use only if you troubleshoot the command itself.</p> <p>★ <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p>                                                                                                                              |
| <code>ctl -h</code>                            | Shows the expected syntax and the list of the available QoS modules.                                                                                                                                                                                                                                                                                                                              |

If this command fails, run the <a href="#">"etmstop" on page 2111</a> and then <a href="#">"etmstart" on page 2110</a> commands.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>log {on   off   stat}</code>                                       | <p>Controls the state of QoS logging in the Security Gateway kernel:</p> <ul style="list-style-type: none"> <li>■ <code>on</code> - Enables the QoS logging (default)</li> <li>■ <code>off</code> - Disables the QoS logging</li> <li>■ <code>stat</code> - Shows the current QoS logging status</li> </ul> <p>You can disable the QoS logging to save resources without reinstalling the QoS policy.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>stat [-h]</code> | <p>Shows the status of the QoS Software Blade and policy on the Security Gateway.</p> <p>The <code>-h</code> parameter shows the built-in usage for the "stat" parameter.</p> <p> <b>Important</b> - This command is outdated and exists only for backward compatibility with very old versions. Use the "<a href="#">cpstat</a>" on page 1033" command.</p> |
| <code>unload</code>    | Uninstalls the QoS Policy from the Security Gateway.                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>ver [-k]</code>  | <p>Shows the QoS Software Blade version.</p> <p>If you specify the <code>-k</code> parameter, the output also shows the kernel version.</p>                                                                                                                                                                                                                                                                                                   |

## Examples

### Example 1 - Fetching the QoS policy based on the \$FWDIR/conf/masters file

```
[Expert@MyGW]# fgate fetch -f
Fetching QoS Software Blade Policy:
Received Policy. Downloading...

eth0(inbound), eth0(outbound).
Download OK.
Done.
[Expert@MyGW]#
```

### Example 2 - Fetching the QoS policy from the Management Server specified by its IP address

```
[Expert@MyGW]# fgate fetch 192.168.3.240
Fetching QoS Software Blade Policy:
Received Policy. Downloading...

eth0(inbound), eth0(outbound).
Download OK.
Done.
[Expert@MyGW]#
```

### Example 3 - Viewing the QoS status

```
[Expert@MyGW]# fgate stat

Product:      QoS Software Blade
Version:      R82.10
Kernel Build: 456
Policy Name:  MyPolicy
Install time: Wed Dec 4 19:53:48 2019
Interfaces Num: 1

Interface table
-----
|Name|Dir|Limit (Bps)|Avg Rate (Bps)|Conns|Pend pkts|Pend bytes|
-----
|eth0|in | 1250000000|          0|    0|        0|         0|
|eth0|out| 1250000000|          0|    0|        0|         0|
-----

[Expert@MyGW]#
```

### Example 4 - Viewing the QoS Software Blade version

```
[Expert@MyGW:0]# fgate ver
This is Check Point QoS Software Blade R82.10 - Build 123
[Expert@MyGW:0]#
[Expert@MyGW:0]# fgate ver -k
This is Check Point QoS Software Blade R82.10 - Build 123
kernel: R82.10 - Build 456
[Expert@MyGW:0]#
```

# IPS Commands

For more information about IPS, see the [R82.10 Threat Prevention Administration Guide](#).

IPS commands let you configure and show the IPS on the Security Gateway without installing a new policy.

**Important** - Changes in the IPS configuration made with these commands are not persistent. If you install a policy or restart the Security Gateway, the changes are deleted.

# ips

## Description

Shows various information about the IPS Software Blade.

Controls the IPS Software Blade.

## Syntax

```
ips
    bypass <options>
    debug <options>
    off
    on
    stat
```

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

## Parameters

| Parameter                           | Description                                                                                 |
|-------------------------------------|---------------------------------------------------------------------------------------------|
| No Parameters                       | Shows the built-in usage.                                                                   |
| <code>bypass &lt;options&gt;</code> | Controls the IPS Bypass mode.<br>See <a href="#">"ips bypass" on page 2122</a> .            |
| <code>debug &lt;options&gt;</code>  | Collects the IPS debug.<br>See <a href="#">"ips debug" on page 2124</a> .                   |
| <code>off</code>                    | Disables the IPS Software Blade on-the-fly.<br>See <a href="#">"ips off" on page 2125</a> . |
| <code>on</code>                     | Enables the IPS Software Blade on-the-fly.<br>See <a href="#">"ips on" on page 2126</a> .   |
| <code>stat</code>                   | Shows the IPS status.<br>See <a href="#">"ips stat" on page 2127</a> .                      |

# ips bypass

## Description

Controls the IPS Bypass mode:

- When CPU and/or Memory utilization reaches the configured higher threshold, IPS Software Blade disables itself.
- When CPU and/or Memory utilization goes down to the configured lower threshold, IPS Software Blade enables itself.

## Syntax

```
ips bypass
  off
  on
  set <options>
  stat
```

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

## Parameters

| Parameter     | Description                          |
|---------------|--------------------------------------|
| No Parameters | Shows the applicable built-in usage. |
| off           | Disables the IPS Bypass mode.        |
| on            | Enables the IPS Bypass mode.         |

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| set<br><options> | <p>Configures the utilization thresholds (in per cent), at which to engage (higher threshold) or disengage (lower threshold) the IPS Bypass mode. The available options are:</p> <ul style="list-style-type: none"> <li>■ Configure the lower CPU threshold:<br/> <pre>ips bypass set cpu low &lt;0-100&gt;</pre> </li> <li>■ Configure the higher CPU threshold:<br/> <pre>ips bypass set cpu high &lt;0-100&gt;</pre> </li> <li>■ Configure the lower Memory threshold:<br/> <pre>ips bypass set mem low &lt;0-100&gt;</pre> </li> <li>■ Configure the higher Memory threshold:<br/> <pre>ips bypass set mem high &lt;0-100&gt;</pre> </li> </ul> <p>Example:</p> <pre>ips bypass set cpu low 80</pre> |
| stat             | <p>Shows the status of the IPS Bypass Under Load:</p> <ul style="list-style-type: none"> <li>■ IPS bypass mode</li> <li>■ CPU thresholds</li> <li>■ Memory thresholds</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

# ips debug

## Description

Collects the IPS debug information.

 **Note** - For information about the kernel debug, see the [R82.10 Security Gateway Guide](#) - Chapter *Kernel Debug on Security Gateway*.

## Syntax

```
ips debug [-e <Filter>] -o <Output File>
```

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

## Parameters

| Parameter        | Description                                                                                                                                                                                               |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -e<br><Filter>   | Specifies the INSPECT filter to capture packets.<br>For more information, see the explanation for the " <a href="#">fw monitor on page 1187</a> " command in <a href="#">sk30583: What is FW Monitor?</a> |
| -o <Output File> | Specifies the path and the name of the output debug file.                                                                                                                                                 |

## Example

```
ips debug -o /var/log/IPS_debug.txt
```

# ips off

## Description

Disables the IPS Software Blade on-the-fly.

**Note** - To enable, run the "[ips on" on page 2126](#)" command.

## Syntax

```
ips off
```

### Important:

- In a Cluster, you must configure all the Cluster Members in the same way.
- On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

## Example 1

```
[Expert@MyGW:0]# ips off
IPS is disabled
Please note that for the configuration to apply for connections from existing templates, you have to run this command with -n flag which
deletes existing templates.
Without '-n', it will fully take effect in a few minutes.
[Expert@MyGW:0]#
```

## Example 2

```
[Expert@MyGW:0]# ips off -n
IPS is disabled
Deleting templates

Clearing table cphwd_tmpl
[Expert@MyGW:0]#
```

# ips on

## Description

Enables the IPS Software Blade on-the-fly, if it was disabled with the "[ips off on page 2125](#)" command.

## Syntax

```
ips on [-n]
```

## Example 1

```
[Expert@MyGW:0]# ips on
IPS is enabled
Please note that for the configuration to apply for connections from existing templates, you have to run this command with -n flag which
deletes existing templates.
Without '-n', it will fully take effect in a few minutes.
[Expert@MyGW:0]#
```

## Example 2

```
[Expert@MyGW:0]# ips on -n
IPS is enabled
Deleting templates

Clearing table cphwd_tmpl
[Expert@MyGW:0]#
```

# ips stat

## Description

Shows this information:

- IPS Status (Enabled or Disabled)
- IPS Update Version
- Global Detect (On or Off)
- Bypass Under Load (On or Off)

## Syntax

```
ips stat
```

**Important** - On Scalable Platforms, you must run the applicable commands in the Expert mode on the applicable Security Group.

## Example

```
[Expert@MyGW:0]# ips stat
Active Profiles:
My_IPS_Profile
IPS Status: Enabled
IPS Update Version: 635158746
Global Detect: Off
Bypass Under Load: Off
[Expert@MyGW:0]#
```

# Monitoring Commands

For more information, see the [R82.10 Logging and Monitoring Administration Guide](#).

This section contains commands for the **Monitoring** Software Blade (former SmartView Monitor) on the Security Gateway / each Cluster Member.

# rtm

## Description

Controls the **Monitoring** Software Blade (former SmartView Monitor) on the Security Gateway / each Cluster Member.

Shows the information about the **Monitoring** Software Blade.

## Syntax

```
rtm
    debug <options>
    drv <options>
    monitor <options>
    rtmd
    stat <options>
    ver <options>
```

Note - "RTM" stands for Real Time Monitoring.

## Parameters

| Parameter                                  | Description                                                                |
|--------------------------------------------|----------------------------------------------------------------------------|
| No Parameters                              | Shows the built-in usage.                                                  |

# rtm debug

## Description

Collects the SmartView Monitor debug information in the `$FWDIR/log/rtmd.elg` file on the Security Gateway / each Cluster Member.

## Syntax

```
rtm debug {on | off} [OPSEC_DEBUG_LEVEL | TDERROR_<AppName>_<Topic>=<ErrLevel>]
```

## Parameters

| Parameter         | Description                               |
|-------------------|-------------------------------------------|
| on                | Start debug mode                          |
| off               | Stop debug mode                           |
| OPSEC_DEBUG_LEVEL | Turn on OPSEC debug printouts             |
| TDERROR_RTM_ALL   | Turn on SmartView Monitor debug printouts |

## Example

```
rtm debug on TDERROR_RTM_ALL=5
```

# rtm drv

## Description

Starts, stops, or shows the status of the SmartView Monitor kernel driver on the Security Gateway / each Cluster Member.

 **Important** - Do not run this command manually. Run the ["rtmstart" on page 2143](#) and ["rtmstop" on page 2144](#) commands.

## Syntax

```
rtm drv
      off
      on
      stat
```

## Parameters

| Parameter | Description                                      |
|-----------|--------------------------------------------------|
| on        | Starts the SmartView Monitor kernel driver       |
| off       | Stops the SmartView Monitor kernel driver        |
| stat      | Shows the SmartView Monitor kernel driver status |

# rtm rtmd

## Description

Starts the SmartView Monitor daemon manually on the Security Gateway / each Cluster Member.

This also occurs manually when you run the *"rtmstart" on page 2143* command.

## Syntax

```
rtm [-d] rtmd
```

## Parameters

| Parameter | Description                                                                                                                                                                                                                                                                                                                                          |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -d        | <p>Runs the command in debug mode.<br/>Use only if you troubleshoot the command itself.</p> <p> <b>Best Practice</b> - If you use this parameter, then redirect the output to a file, or use the <a href="#">script</a> command to save the entire CLI session.</p> |

# rtm monitor

## Description

Starts the monitoring process for an interface or a Virtual Link on the Security Gateway / each Cluster Member.

If options and grouping are not used, this command monitors all traffic, on all interfaces, in both directions.

## Syntax

```
rtm monitor vl <Virtual_Link_Name> [-t {wire | application}] [-h
<Module>]
```

```
rtm monitor <Key_1> [<Key_2> [<Key_3>] [<Key_4>]] <Value_Column_1>
[<Value_Column_2> [<Value_Column_3>] [<Value_Column_4>] [<Value_
Column_5>] [<Value_Column_6>]] [<Filter>] [<Options>]
```

## Parameters

| Parameter               | Description                                                                                                                                                                                                                                                                  |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| No Parameters           | Shows the built-in usage and examples.                                                                                                                                                                                                                                       |
| <Virtual_Link_Name>     | Specifies the name of the monitored Virtual Link.                                                                                                                                                                                                                            |
| -t {wire   application} | Specifies how to show the data: <ul style="list-style-type: none"> <li>■ <b>wire</b> - Shows the data on the wire after compression, or encryption.</li> <li>■ <b>application</b> - Shows the data as the application sees it (not compressed and not encrypted).</li> </ul> |
| -h <Module>             | Specifies the Security Gateway by its IP address, or resolvable hostname.                                                                                                                                                                                                    |
| <Key_1> [... [<Key_4>]] | Specifies up to four keys in this format:<br>-k <Key_Type> [<Key_Atrr>] [<Entity_1> ... <Entity_N>]                                                                                                                                                                          |

| Parameter                                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <Options> | <p>Specifies these options:</p> <ul style="list-style-type: none"> <li>■ <code>-e &lt;Export File Name&gt;</code><br/>Specifies the path and the name of the file, in which the command saves its output.</li> <li>■ <code>-h &lt;Module&gt;</code><br/>Specifies the Security Gateway by its IP address, or resolvable hostname.<br/>Default is <code>localhost</code>.</li> <li>■ <code>-i &lt;Interval in Seconds&gt;</code><br/>The command runs in the loop and shows the output every specified number of seconds.<br/>Default is 2 sec.</li> <li>■ <code>-m {raw   resolve   both}</code><br/>Specifies how to resolve the names.<br/>Default is <code>both</code>.</li> <li>■ <code>-s {top   bottom   none} [index=&lt;1...6&gt;] [updates=&lt;1...200&gt;]</code><br/>Specifies how to sort the output.<br/>If you specify <code>none</code>, the defaults are:<br/><code>index=1</code> and <code>updates=50</code>.</li> </ul> |

## Notes

- Use the tilde character "~" to specify a subrule (`rule~~subrule`).

To monitor for the QoS Policy, use: `rule~~fgrule`

- The specified entities correspond to the specified grouping option.

For example, if the monitoring process works according to a service (`svc`), add all the monitored services, separated by a space.

## Examples

### Example 1

This command shows top services (based on bytes per seconds) on external interfaces in the inbound direction:

```
rtm monitor -f interface external,in -k svc -v wb
```

## Example 2

This command shows top Access Control rules (based on average concurrent connections):

```
rtm monitor -k fwrule -v conn acc=concurrent
```

## Example 3

This command shows Individual HTTP connections (bytes per second):

```
rtm monitor -f svc http -k svc -k connId -v wb
```

## Example 4

This command shows bottom inbound IP addresses versus outbound IP addresses (based on packets per interval):

```
rtm monitor -k ip -v pkt dir=in acc=sum -v pkt dir=out acc=sum -  
v pkt acc=sum sort=bottom -i 10
```

## Example 5

This command shows top tunnels (based on average concurrent connections):

```
rtm monitor -f tunnelType not 0 -k tunnel -k tunnelType -v conn  
-m resolve
```

## Example 6

This command shows packet size distribution (based on packets per interval):

```
rtm monitor -k pktRange 0-99 100-499 500-999 1000-1999 ">2000" -  
v pkt acc=sum -i 1
```

## Example 7

This command shows top URLs (based on sessions per seconds) - host part only:

```
rtm monitor -k url url_mod=host -v session
```

# rtm stat

## Description

Show this information on the Security Gateway / each Cluster Member:

- The status of the Monitoring Software Blade
- The status of the SmartView Monitor daemon
- The status of the SmartView Monitor driver
- Number of opened Virtual Links
- Number of opened Views
- Some performance counters

## Syntax

```
rtm stat -h
```

```
rtm stat [vl | view] [perf [{on | off | reset}] [-i <Interval>] [-r <View_ID>] [-v[v] [v]]
```

## Parameters

| Parameter                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -h                        | Shows the built-in usage.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| vl                        | Shows current Virtual Links                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| view                      | Shows current Views                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| perf [{off   on   reset}] | <p>Controls whether to show performance information:</p> <ul style="list-style-type: none"> <li>▪ off - Disables the feature</li> <li>▪ on - Enables the feature</li> <li>▪ reset - Resets the counters</li> </ul> <p>The output shows these performance counters:</p> <ul style="list-style-type: none"> <li>▪ New Connections</li> <li>▪ Packets</li> <li>▪ Inf Reclassify</li> <li>▪ View Reclassify</li> <li>▪ End Connections</li> <li>▪ Packets / connections ratio</li> </ul> |

| Parameter                        | Description                                                                                                                                                                                               |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-i &lt;Interval&gt;</code> | The command runs in the loop and shows the output every specified number of seconds.                                                                                                                      |
| <code>-r &lt;View_ID&gt;</code>  | Specifies the View ID to show.                                                                                                                                                                            |
| <code>-v[v][v]</code>            | Verbose output: <ul style="list-style-type: none"> <li>▪ <code>-v</code> - Verbose output</li> <li>▪ <code>-vv</code> - More verbose output</li> <li>▪ <code>-vvv</code> - Most verbose output</li> </ul> |

## Examples

### Example 1

```
[Expert@MyGW:0]# rtm stat
-----
SmartView Monitor Status:   Sun Mar 20 18:25:51 2022
-----
Product is Enabled
Daemon is ON
-----
Status for kernel instance 0
-----
Driver is ON
Open Virtual-Links: 0
Open Views: 0
-----
Status for kernel instance 1
-----
Driver is ON
Open Virtual-Links: 0
Open Views: 0
-----
Status for kernel instance ...
-----
... (truncated for brevity) ...
[Expert@MyGW:0]#
```

**Example 2**

```

[Expert@MyGW:0]# rtm stat view -vvv
-----
SmartView Monitor Status:   Sun Mar 20 18:25:51 2022
-----
Product is Enabled
Daemon is ON
-----
Status for kernel instance 0
-----
Driver is ON
Open Virtual-Links: 0
Open Views: 0
-----
Status for kernel instance 1
-----
Driver is ON
Open Virtual-Links: 0
Open Views: 0
-----
Status for kernel instance ...
-----
... (truncated for brevity) ...
-----
VIEW 1:  svc                |  wb(rate)          interval: 2    Seconds
        60016,60016         |  5148
        11008a,11008a       |  229
        Aggregate           |  5377

        Number of Entries(2)
        Keys(-k svc acc=replace )

        Daemon id:5          kernel id:0 timeUntilUpdate: 1 [Sec]
-----
[Expert@MyGW:0]#

```

## rtm ver

### Description

Shows the SmartView Monitor version on the Security Gateway / each Cluster Member.

### Syntax

```
rtm ver [-k]
```

### Parameters

| Parameter | Description                                 |
|-----------|---------------------------------------------|
| -k        | Shows the SmartView Monitor kernel version. |

# rtmstart

## Description

Loads the SmartView Monitor kernel module and starts the SmartView Monitor daemon on the Security Gateway / each Cluster Member.

## Syntax

```
rtmstart
```

# rtmstop

## Description

Kills the SmartView Monitor daemon and unloads the SmartView Monitor kernel module on the Security Gateway / each Cluster Member.

## Syntax

```
rtmstop
```

# Appendix

## Lightshot Snapshot

Each Regular Gaia Snapshot and each Scheduled Gaia Snapshot requires significant disk space (more than 12 gigabytes on a Security Gateway, more than 30 gigabytes on a VSX Gateway). It takes a long time to create these Gaia Snapshots.

Starting in R82, Gaia OS has an additional feature - Lightshot Snapshot. This snapshot type saves only the delta of the disk partition. As a result, it takes less disk space and less time to create each Lightshot Snapshot. The smaller the delta between the current state of the disk partition and the previous Lightshot Snapshot, the less disk space and less time are required.

See the [\*R82.10 Gaia Administration Guide\*](#).

# Working with Kernel Parameters

See the [R82.10 Security Gateway Guide](#) > Chapter "Working with Kernel Parameters".

# Running Check Point Commands in Shell Scripts

To run Check Point commands in your shell scripts, it is necessary to add the calls to the required Check Point shell scripts.

You must add these calls below the top line `#!/bin/bash`.

## On a Security Management Server / Log Server / SmartEvent Server

You must add the call to the `/etc/profile.d/CP.sh` script.

```
#!/bin/bash

source /etc/profile.d/CP.sh

<Applicable Check Point Commands>

[mandatory last new line]
```

## On a Multi-Domain Server / Multi-Domain Log Server

You must add the calls to these scripts (in the order listed below):

1. `/etc/profile.d/CP.sh`
2. `$MDSDIR/scripts/MDSprofile.sh`
3. `$MDS_SYSTEM/shared/mds_environment_utils.sh`
4. `$MDS_SYSTEM/shared/sh_utilities.sh`

```
#!/bin/bash

source /etc/profile.d/CP.sh
source $MDSDIR/scripts/MDSprofile.sh
source $MDS_SYSTEM/shared/mds_environment_utils.sh
source $MDS_SYSTEM/shared/sh_utilities.sh

<Applicable Check Point Commands>

[mandatory last new line]
```

## On a Security Gateway / Cluster Members (non-VSX)

You must add the call to the `/etc/profile.d/CP.sh` script.

```
#!/bin/bash

source /etc/profile.d/CP.sh

<Applicable Check Point Commands>

[mandatory last new line]
```

# On a VSX Gateway / VSX Cluster Members

You must add the calls to these scripts (in the order listed below):

1. `/etc/profile.d/CP.sh`
2. `/etc/profile.d/vsenv.sh`

```
#!/bin/bash

source /etc/profile.d/CP.sh
source /etc/profile.d/vsenv.sh

<Applicable Check Point Commands>

[mandatory last new line]
```

# Loading User-Defined Environment Variables

To load your shell variables, these options exist:

- Configure your shell variables explicitly in your shell script:

```
#!/bin/bash

#Check Point Variables
source <Required Check Point shell scripts>

#User-Defined Variables
Your_Variable=Your_Value

<Applicable Check Point Commands>

[mandatory last new line]
```

- Configure your shell variables in a dedicated shell script and call it:

```
#!/bin/bash

#Check Point Variables
source <Required Check Point shell scripts>

#User-Defined Variables
source /<Path>/<Name-of-Your-Script-with-Shell-Variables>.sh

<Applicable Check Point Commands>

[mandatory last new line]
```

# Glossary

## #

---

### 3rd-party Cluster

Cluster of Check Point Firewalls that work together in a redundant configuration. These Check Point Firewalls are installed on an operating system other than [%Vars\_Other.r\_gaia%]. VRRP Cluster on [%Vars\_Other.r\_gaia%] OS is also considered a 3rd-party cluster. The 3rd-party cluster handles the traffic, and Check Point Firewalls perform only State Synchronization.

## A

---

### Accelerated Path

Packet flow on the Host appliance, when the packet is completely handled by the SecureXL device. It is processed and forwarded to the network.

### Access Role

Access Role objects let you configure network access according to: Networks, Users and user groups, Computers and computer groups, Remote Access Clients. After you activate the Identity Awareness Software Blade, you can create Access Role objects and use them in the Source and Destination columns of Access Control Policy rules.

### Active

State of a Cluster Member that is fully operational: (1) In ClusterXL, this applies to the state of the Check Point Firewall (2) In 3rd-party / OPSEC cluster, this applies to the state of the cluster State Synchronization mechanism.

### Active-Active

A cluster mode (in versions R80.40 and higher), where Cluster Members are located in different geographical areas (different sites, different cloud availability zones). This mode supports the configuration of IP addresses from different subnets on all cluster interfaces, including the Sync interfaces. Each Cluster Member inspects all traffic routed to it and synchronizes the recorded connections to its peer Cluster Members. The traffic is not balanced between the Cluster Members.

### Active Domain Server

The only Domain Management Server in a Management High Availability deployment that can manage a specified Domain.

**Active Security Management Server**

The Management Server in Management High Availability that is currently configured as Active.

**Active Up**

ClusterXL in High Availability mode that was configured as Maintain current active Cluster Member in the cluster object in SmartConsole: (1) If the current Active member fails for some reason, or is rebooted (for example, Member\_A), then failover occurs between Cluster Members - another Standby member will be promoted to be Active (for example, Member\_B). (2) When former Active member (Member\_A) recovers from a failure, or boots, the former Standby member (Member\_B) will remain to be in Active state (and Member\_A will assume the Standby state).

**Active(!)**

In ClusterXL, state of the Active Cluster Member that suffers from a failure. A problem was detected, but the Cluster Member still forwards packets, because it is the only member in the cluster, or because there are no other Active members in the cluster. In any other situation, the state of the member is Down. Possible states: ACTIVE(!), ACTIVE(!F) - Cluster Member is in the freeze state, ACTIVE(!P) - This is the Pivot Cluster Member in the Load Sharing Unicast mode, ACTIVE(!FP) - This is the Pivot Cluster Member in the Load Sharing Unicast mode and it is in the freeze state.

**AD Query**

Check Point clientless identity acquisition tool. It is based on Active Directory integration and it is completely transparent to the user. The technology is based on querying the Active Directory Security Event Logs and extracting the user and computer mapping to the network address from them. It is based on Windows Management Instrumentation (WMI), a standard Microsoft protocol. The Check Point Firewall with Identity Awareness enabled communicates directly with the Active Directory domain controllers and does not require a separate server. No installation is necessary on the clients, or on the Active Directory server.

**Affinity**

The assignment of a specified CoreXL Firewall instance, Traditional VSX Virtual System, interface, user space process, or IRQ to one or more specified CPU cores.

**Anti-Bot**

Software Blade on a Check Point Firewall that blocks botnet behavior and communication to Command and Control (C&C) centers. Acronyms: AB, ABOT.

**Anti-Spam**

Software Blade on a Check Point Firewall that provides comprehensive protection for email inspection. Synonym: Anti-Spam & Email Security. Acronyms: AS, ASPAM.

**Anti-Virus**

Software Blade on a Check Point Firewall that uses real-time virus signatures and anomaly-based protections from ThreatCloud to detect and block malware at the Check Point Firewall before users are affected. Acronym: AV.

**Application Control**

Software Blade on a Check Point Firewall that allows granular control over specific web-enabled applications by using deep packet inspection. Acronym: APPI.

**ARP Forwarding**

Forwarding of ARP Request and ARP Reply packets between Cluster Members by encapsulating them in Cluster Control Protocol (CCP) packets. Introduced in R80.10 version.

**Ask**

UserCheck rule action that blocks traffic and files and shows a UserCheck message. The user can agree to allow the activity.

**Audit Log**

Log that contains administrator actions on a Management Server (login and logout, creation or modification of an object, installation of a policy, and so on).

**B**

---

**Backup**

(1) In VRRP Cluster on Gaia OS - State of a Cluster Member that is ready to be promoted to Master state (if Master member fails). (2) In Traditional VSX Cluster configured in the Virtual System Load Sharing mode with three or more Cluster Members - State of a Virtual System on a third (and so on) Traditional VSX Cluster Member. (3) A Cluster Member or Virtual System in this state does not process any traffic passing through cluster.

**Blocking Mode**

Cluster operation mode, in which Cluster Member does not forward any traffic (for example, caused by a failure).

**Bot**

Malicious software that neutralizes Anti-Virus defenses, connects to a Command and Control center for instructions from cyber criminals, and carries out the instructions.

**Bridge Mode**

Check Point Firewall or Virtual System that works as a Layer 2 bridge device for easy deployment in an existing topology.

**Browser-Based Authentication**

Authentication of users in Check Point Identity Awareness web portal - Captive Portal, to which users connect with their web browser to log in and authenticate.

**Burstiness**

Data that is transferred or transmitted in short, uneven spurts. LAN traffic is typically bursty. Opposite of streaming data.

**C**

---

**Captive Portal**

A Check Point Identity Awareness web portal, to which users connect with their web browser to log in and authenticate, when using Browser-Based Authentication.

**Check Point Firewall**

Dedicated Check Point server that runs Check Point software to inspect traffic and enforce Security Policies for connected network resources. Formerly: Security Gateway.

**Cloud Credentials**

Specific credentials from identity providers used by the Identity Collector to connect seamlessly to the Check Point Portal. These credentials are essential for establishing a secure and efficient connection between the Identity Client and the Check Point Portal.

**Cloud Services**

Refers to a centralized identities solution provided by Identity and Trust and Directory Sync. These services offer identity management and directory synchronization capabilities, hosted and managed in the cloud.

**Cluster**

Two or more Check Point Firewalls that work together in a redundant configuration - High Availability, or Load Sharing.

**Cluster Control Protocol**

Proprietary Check Point protocol that runs between Cluster Members on UDP port 8116, and has the following roles: (1) State Synchronization (Delta Sync), (2) Health checks (state of Cluster Members and of cluster interfaces): Health-status Reports, Cluster-member Probing, State-change Commands, Querying for cluster membership. Note: CCP is located between the Check Point Firewall kernel and the network interface (therefore, only TCPdump should be used for capturing this traffic). Acronym: CCP.

**Cluster Correction Layer**

Proprietary Check Point mechanism that deals with asymmetric connections in Check Point cluster. The CCL provides connections stickiness by "correcting" the packets to the correct Cluster Member: In most cases, the CCL makes the correction from the CoreXL SND. In some cases (like Dynamic Routing, or VPN), the CCL makes the correction from the Firewall or SecureXL. Acronym: CCL.

**Cluster Interface**

An interface on a Cluster Member, whose Network Type was set as Cluster in SmartConsole in cluster object. This interface is monitored by cluster, and failure on this interface will cause cluster failover.

**Cluster Member**

Check Point Firewall that is part of a cluster.

**Cluster Mode**

Configuration of Cluster Members to work in these redundant modes: (1) One Cluster Member processes all the traffic - High Availability or VRRP mode (2) All traffic is processed in parallel by all Cluster Members - Load Sharing.

**Cluster Topology**

Set of interfaces on all members of a cluster and their settings (Network Objective, IP address / Net Mask, Topology, Anti-Spoofing, and so on).

**ClusterXL**

Cluster of Check Point Firewalls that work together in a redundant configuration. The ClusterXL both handles the traffic and performs State Synchronization. These Check Point Firewalls are installed on Gaia OS: (1) ClusterXL supports up to 5 Cluster Members, (2) VRRP Cluster supports up to 2 Cluster Members, (3) Traditional VSX VSLs Cluster supports up to 13 Cluster Members. Note: In the ClusterXL Load Sharing mode, configuring more than 4 Cluster Members significantly decreases the cluster performance due to amount of Delta Sync traffic.

**Compliance**

Software Blade on a Management Server to view and apply the Security Best Practices to the managed Check Point Firewalls. This Software Blade includes a library of Check Point-defined Security Best Practices to use as a baseline for good Check Point Firewall and Policy configuration.

**Content Awareness**

Software Blade on a Check Point Firewall that provides data visibility and enforcement. Acronym: CTNT.

**Cooperative Enforcement**

Integration of an on-premises Endpoint Security Management Server and Check Point Firewall.

**CoreXL**

Performance-enhancing technology for Check Point Firewalls on multi-core processing platforms. Multiple Check Point Firewall instances are running in parallel on multiple CPU cores.

**CoreXL Dynamic Dispatcher**

Improved CoreXL SND feature. Part of CoreXL that distributes packets between CoreXL Firewall instances. Traffic distribution between CoreXL Firewall instances is dynamically based on the utilization of CPU cores, on which the CoreXL Firewall instances are running. The dynamic decision is made for first packets of connections, by assigning each of the CoreXL Firewall instances a rank, and selecting the CoreXL Firewall instance with the lowest rank. The rank for each CoreXL Firewall instance is calculated according to its CPU utilization. The higher the CPU utilization, the higher the CoreXL Firewall instance's rank is, hence this CoreXL Firewall instance is less likely to be selected by the CoreXL SND.

**CoreXL Firewall Instance**

On a Check Point Firewall with CoreXL enabled, the Firewall kernel is copied multiple times. Each replicated copy, or firewall instance, runs on one processing CPU core. These firewall instances handle traffic at the same time, and each firewall instance is a complete and independent firewall inspection kernel. Synonym: CoreXL FW Instance.

**CoreXL SND**

Secure Network Distributor. Part of CoreXL that is responsible for: Processing incoming traffic from the network interfaces; Securely accelerating authorized packets (if SecureXL is enabled); Distributing non-accelerated packets between Firewall kernel instances (SND maintains global dispatching table, which maps connections that were assigned to CoreXL Firewall instances). Traffic distribution between CoreXL Firewall instances is statically based on Source IP addresses, Destination IP addresses, and the IP 'Protocol' type. The CoreXL SND does not really "touch" packets. The decision to stick to a particular FWK daemon is done at the first packet of connection on a very high level, before anything else. Depending on the SecureXL settings, and in most of the cases, the SecureXL can be offloading decryption calculations. However, in some other cases, such as with Route-Based VPN, it is done by FWK daemon.

**CPHA**

General term in Check Point Cluster that stands for Check Point High Availability (historic fact: the first release of ClusterXL supported only the High Availability mode) that is used only for internal references (for example, inside kernel debug) to designate ClusterXL infrastructure.

**CPUSE**

Check Point Upgrade Service Engine for Gaia Operating System. With CPUSE, you can automatically update Check Point products for the Gaia OS, and the Gaia OS itself.

**Critical Device**

A special software device on each Cluster Member, through which the critical aspects for cluster operation are monitored. When the critical monitored component on a Cluster Member fails to report its state on time, or when its state is reported as problematic, the state of that member is immediately changed to Down. The complete list of the configured critical devices (pnotes) is printed by the 'cphaprob -ia list' command or 'show cluster members pnotes all' command. Synonyms: Pnote, Problem Notification.

**Custom Report**

User-defined report for a Check Point product, typically based on a predefined report.

**D**

---

**DAIP Firewall**

Check Point Firewall with a Dynamically Assigned IP (DAIP) is a server, on which the IP address of the external interface is assigned dynamically (by a DHCP server, by an ISP).

**Data Loss Prevention**

Software Blade on a Check Point Firewall that detects and prevents the unauthorized transmission of confidential information outside the organization. Acronym: DLP.

**Data Type**

Classification of data in a Check Point Security Policy for the Content Awareness Software Blade.

**Dead**

State reported by a Cluster Member when it goes out of the cluster (due to 'cphastop' command (which is a part of 'cpstop'), or reboot).

**Decision Function**

A special cluster algorithm applied by each Cluster Member on the incoming traffic in order to decide, which Cluster Member should process the received packet. Each Cluster Member maintains a table of hash values generated based on connections tuple (source and destination IP addresses/Ports, and Protocol number).

**Dedicated Management Interface**

Separate physical interface on Traditional VSX Gateway or Traditional VSX Cluster Members, through which Check Point Security Management Server or Multi-Domain Security Management Server connects directly to Traditional VSX Gateway or Traditional VSX Cluster Members. DMI is restricted to management traffic, such as provisioning, logging and monitoring. Acronym: DMI.

**Delta Sync**

Synchronization of kernel tables between all working Cluster Members - exchange of CCP packets that carry pieces of information about different connections and operations that should be performed on these connections in relevant kernel tables. This Delta Sync process is performed directly by Check Point kernel. While performing Full Sync, the Delta Sync updates are not processed and saved in kernel memory. After Full Sync is complete, the Delta Sync packets stored during the Full Sync phase are applied by order of arrival.

**Delta Sync Retransmission**

It is possible that Delta Sync packets will be lost or corrupted during the Delta Sync operations. In such cases, it is required to make sure the Delta Sync packet is re-sent. The Cluster Member requests the sending Cluster Member to retransmit the lost/corrupted Delta Sync packet. Each Delta Sync packet has a sequence number. The sending member has a queue of sent Delta Sync packets. Each Cluster Member has a queue of packets sent from each of the peer Cluster Members. If, for any reason, a Delta Sync packet was not received by a Cluster Member, it can ask for a retransmission of this packet from the sending member. The Delta Sync retransmission mechanism is somewhat similar to a TCP Window and TCP retransmission mechanism. When a member requests retransmission of Delta Sync packet, which no longer exists on the sending member, the member prints a console messages that the sync is not complete.

**Detect**

UserCheck rule action that allows traffic and files to enter the internal network and logs them.

**Directory Sync**

A solution that holds static Directory information regarding users, groups, devices, and memberships. .

**Distributed Deployment**

Configuration in which the Check Point Firewall and the Security Management Server products are installed on different servers.

**Domain Dedicated Log Server**

Dedicated Log Server (not a Domain Log Server) configured in a specified Domain (in versions R81 and higher). It stores and processes logs from Check Point Firewalls that are managed by the corresponding Domain Management Server. Acronym: DDLS.

**Domain Dedicated SmartEvent Server**

Dedicated SmartEvent Server configured in a specified Domain (in versions R81 and higher). It hosts the events database for logs from Check Point Firewalls that are managed by the corresponding Domain Management Server.

**Domain Management Server**

Virtual Security Management Server that manages Check Point Firewalls for one Domain, as part of a Multi-Domain Security Management environment. Acronym: DMS.

**Down**

State of a Cluster Member during a failure when one of the Critical Devices reports its state as "problem": In ClusterXL, applies to the state of the Check Point Firewall; in 3rd-party / OPSEC cluster, applies to the state of the State Synchronization mechanism. A Cluster Member in this state does not process any traffic passing through cluster.

**Dying**

State of a Cluster Member as assumed by peer members, if it did not report its state for 0.7 second.

**Dynamic Object**

Special object type, whose IP address is not known in advance. The Check Point Firewall resolves the IP address of this object in real time.

**E**

---

**Encryption Domain**

The networks that a Check Point Firewall protects and for which it encrypts and decrypts VPN traffic.

**Endpoint Policy Management**

Software Blade on a Management Server to manage an on-premises Endpoint Security environment.

**Event**

Record of a security or network incident that is based on one or more logs, and on a customizable set of rules that are defined in the Event Policy.

**Event Correlation**

Procedure that extracts, aggregates, correlates, and analyzes events from the logs.

**Event Policy**

Set of rules that define the behavior of SmartEvent.

**Expert Mode**

The name of the elevated command line shell that gives full system root permissions in the Check Point Gaia operating system.

## F

---

### F2F

Denotes non-VPN connections that SecureXL forwarded to firewall. See "Firewall Path".

### Failback

Recovery of a Cluster Member that suffered from a failure. The state of a recovered Cluster Member is changed from Down to either Active, or Standby (depending on the Cluster Mode). Synonym: Failback.

### Failed Member

A Cluster Member that cannot send or accept traffic because of a hardware or software problem.

### Failover

Transferring of a control over traffic (packet filtering) from a Cluster Member that suffered a failure to another Cluster Member (based on internal cluster algorithms). Synonym: Fail-over.

### Failure

A hardware or software problem that causes a Check Point Firewall to be unable to serve as a Cluster Member (for example, one of cluster interface has failed, or one of the monitored daemon has crashed). Cluster Member that suffered from a failure is declared as failed, and its state is changed to Down (a physical interface is considered Down only if all configured VLANs on that physical interface are Down).

### Firewall Path

Packet flow on the Host Security Appliance, when the SecureXL device is unable to process the packet. The packet is passed to the CoreXL layer and then to one of the CoreXL Firewall instances for full processing. This path also processes all packets when SecureXL is disabled. Synonym: Slow Path.

### Flapping

Consequent changes in the state of either cluster interfaces (cluster interface flapping), or Cluster Members (Cluster Member flapping). Such consequent changes in the state are seen in the 'Logs & Monitor' > 'Logs' (if in SmartConsole > cluster object, the cluster administrator set the 'Track changes in the status of cluster members' to 'Log').

**Flush and ACK**

Cluster Member forces the Delta Sync packet about the incoming packet and waiting for acknowledgments from all other Active members and only then allows the incoming packet to pass through. In some scenarios, it is required that some information, written into the kernel tables, will be Sync-ed promptly, or else a race condition can occur. The race condition may occur if a packet that caused a certain change in kernel tables left Member\_A toward its destination and then the return packet tries to go through Member\_B. In general, this kind of situation is called asymmetric routing. What may happen in this scenario is that the return packet arrives at Member\_B before the changes induced by this packet were Sync-ed to this Member\_B. Example of such a case is when a SYN packet goes through Member\_A, causing multiple changes in the kernel tables and then leaves to a server. The SYN-ACK packet from a server arrives at Member\_B, but the connection itself was not Sync-ed yet. In this condition, the Member\_B will drop the packet as an Out-of-State packet (First packet isn't SYN). In order to prevent such conditions, it is possible to use the "Flush and ACK" (F&A) mechanism. This mechanism can send the Delta Sync packets with all the changes accumulated so far in the Sync buffer to the other Cluster Members, hold the original packet that induced these changes and wait for acknowledgment from all other (Active) Cluster Members that they received the information in the Delta Sync packet. When all acknowledgments arrived, the mechanism will release the held original packet. This ensures that by the time the return packet arrived from a server at the cluster, all the Cluster Members are aware of the connection. F&A is being operated at the end of the Inbound chain and at the end of the Outbound chain (it is more common at the Outbound). Synonyms: FnA, F&A.

**Forwarding**

Process of transferring of an incoming traffic from one Cluster Member to another Cluster Member for processing. There are two types of forwarding the incoming traffic between Cluster Members - Packet forwarding and Chain forwarding. For more information, see "Forwarding Layer in Cluster" and "ARP Forwarding".

**Forwarding Layer**

The Forwarding Layer is a ClusterXL mechanism that allows a Cluster Member to pass packets to peer Cluster Members, after they have been locally inspected by the firewall. This feature allows connections to be opened from a Cluster Member to an external host. Packets originated by Cluster Members are hidden behind the Cluster Virtual IP address. Thus, a reply from an external host is sent to the cluster, and not directly to the source Cluster Member. This can pose problems in the following situations: (1) The cluster is working in High Availability mode, and the connection is opened from the Standby Cluster Member. All packets from the external host are handled by the Active Cluster Member, instead. (2) The cluster is working in a Load Sharing mode, and the decision function has selected another Cluster Member to handle this connection. This can happen since packets directed at a Cluster IP address are distributed between Cluster Members as with any other connection. If a Cluster Member decides, upon the completion of the firewall inspection process, that a packet is intended for another Cluster Member, it can use the Forwarding Layer to hand the packet over to that Cluster Member. In the High Availability mode, packets are forwarded over a Synchronization network directly to peer Cluster Members. It is important to use secured networks only, as encrypted packets are decrypted during the inspection process, and are forwarded as clear-text (unencrypted) data. In the Load Sharing mode, packets are forwarded over a regular traffic network. Packets that are sent on the Forwarding Layer use a special source MAC address to inform the receiving Cluster Member that they have already been inspected by another Cluster Member. Thus, the receiving Cluster Member can safely hand over these packets to the local Operating System, without further inspection.

**Full High Availability**

A special Cluster Mode supported only on Check Point appliances running Gaia OS (R75.40 and higher) or SecurePlatform OS (R77.30 and lower), where each Cluster Member also runs as a Security Management Server. This provides redundancy both between Check Point Firewalls (only the High Availability mode is supported) and between Security Management Servers (only the High Availability mode is supported). Synonyms: Full HA Cluster Mode, Full HA, FullHA.

**Full Sync**

Process of full synchronization of applicable kernel tables by a Cluster Member from the working Cluster Member(s) when it tries to join the existing cluster. This process is meant to fetch a "snapshot" of the applicable kernel tables of already Active Cluster Member(s). Full Sync is performed during the initialization of Check Point software (during boot process, the first time the Cluster Member runs policy installation, during 'cpstart', during 'cphastart'). Until the Full Sync process completes successfully, this Cluster Member remains in the Down state, because until it is fully synchronized with other Cluster Members, it cannot function as a Cluster Member. Meanwhile, the Delta Sync packets continue to arrive, and the Cluster Member that tries to join the existing cluster, stores them in the kernel memory until the Full Sync completes. The whole Full Sync process is performed by fwd daemons on TCP port 256 over the Sync network (if it fails over the Sync network, it tries the other cluster interfaces). The information is sent by fwd daemons in chunks, while making sure they confirm getting the information before sending the next chunk. Also see "Delta Sync".

**G**

---

**Gaia**

Check Point security operating system that combines the strengths of both SecurePlatform and IPSO operating systems.

**Gaia Clish**

The name of the default command line shell in Check Point Gaia operating system. This is a restricted shell (role-based administration controls the number of commands available in the shell).

**Gaia Portal**

Web interface for the Check Point Gaia operating system.

**Geo Cluster**

A High Availability cluster mode (in versions R81.20 and higher), where Cluster Members are located in different cloud availability zones. This mode supports the configuration of IP addresses from different subnets on all cluster interfaces, including the Sync interfaces. The Active Cluster Member inspects all traffic routed to the cluster and synchronizes the recorded connections to its peer Cluster Members. The traffic is not balanced between the Cluster Members. See "High Availability".

**Global Domain**

Domain on a Multi-Domain Security Management Server, on which the Multi-Domain Security Management Server administrator creates and manages objects, security policies and settings that apply to the entire Multi-Domain Security Management environment.

**Global Objects**

On a Multi-Domain Security Management Server, all objects defined in the Global Domain. You can use this objects in a Global Policy or Local Policies on Domains.

**Global Policy**

On a Multi-Domain Security Management Server, a policy defined in the Global Domain. You can assigns this Global Policy to Domains.

**H**

---

**HA not started**

Output of the 'cphaprob <flag>' command or 'show cluster <option>' command on the Cluster Member. This output means that Check Point clustering software is not started on this Check Point Firewall (for example, this machine is not a part of a cluster, or 'cphastop' command was run, or some failure occurred that prevented the ClusterXL product from starting correctly).

**High Availability**

A redundant cluster mode, where only one Cluster Member (Active member) processes all the traffic, while other Cluster Members (Standby members) are ready to be promoted to Active state if the current Active member fails. In the High Availability mode, the Cluster Virtual IP address (that represents the cluster on that network) is associated: (1) With physical MAC Address of Active member (2) With virtual MAC Address. Synonym: Active/Standby. Acronym: HA.

**Hotfix**

Software package installed on top of the current software version to fix a wrong or undesired behavior, and to add a new behavior.

**HTTPS Inspection**

Feature on a Check Point Firewall that inspects traffic encrypted by the Secure Sockets Layer (SSL) protocol for malware or suspicious patterns. Synonym: SSL Inspection. Acronyms: HTTPSI, HTTPSi.

**HTU**

Stands for "HA Time Unit". All internal time in ClusterXL is measured in HTUs (the times in cluster debug also appear in HTUs). Formula in the Check Point software:  $1 \text{ HTU} = 10 \times \text{fw\_timer\_base\_res} = 10 \times 10 \text{ milliseconds} = 100 \text{ ms}$ .

**Hybrid**

Starting in R80.20, on Check Point Firewalls with 40 or more CPU cores, Software Blades run in the user space (as 'fwk' processes). The Hybrid Mode refers to the state when you upgrade Cluster Members from R80.10 (or lower) to R80.20 (or higher). The Hybrid Mode is the state, in which the upgraded Cluster Members already run their Software Blades in the user space (as "fwk" processes), while other Cluster Members still run their Software Blades in the kernel space (represented by the fw\_worker processes). In the Hybrid Mode, Cluster Members are able to synchronize the required information.

**I**

---

**ICA**

Internal Certificate Authority. A component on Check Point Management Server that issues certificates for authentication.

**ICAP Client**

The ICAP Client functionality in a Check Point Firewall that enables it to interact with an ICAP Server responses (see RFC 3507), modify their content, and block the matched HTTP connections.

**ICAP Server**

The ICAP Server functionality in a Check Point Firewall that enables it to interact with an ICAP Client requests, send the files for inspection, and return the verdict.

**Identity Agent**

Check Point dedicated client agent installed on Windows-based user endpoint computers. This Identity Agent acquires and reports identities to the Check Point Firewall with Identity Awareness enabled. The administrator configures the Identity Agents (not the end users). There are two types of Identity Agents - Full and Light. You can download the Full and Light Identity Agent package from the Captive Portal - '[https://<Gateway\\_IP\\_Address>/connect](https://<Gateway_IP_Address>/connect)' or from Support Center.

**Identity Agent Configuration Utility**

Check Point utility that creates custom Identity Agent installation packages. This utility is installed as a part of the Identity Agent: go to the Windows Start menu > All Programs > Check Point > Identity Agent > open the 'Identity Agent' shortcut > select 'Properties' > click 'Open File Location' ('Find Target' in some Windows versions > double-click 'IAConfigTool.exe').

**Identity Agent Distributed Configuration Tool**

Check Point Identity Agent control tool for Windows-based client computers that are members of an Active Directory domain. The Distributed Configuration tool lets you configure connectivity and trust rules for Identity Agents - to which `Vars_BladesFeatures.tp_cpfws` the Identity Agent should connect, depending on its IPv4 / IPv6 address, or Active Directory Site. This tool is installed a part of the Identity Agent: go to the Windows Start menu > All Programs > Check Point > Identity Agent > open 'Distributed Configuration'. Note - You must have administrative access to this Active Directory domain to allow automatic creation of new LDAP keys and writing.

**Identity Awareness**

Software Blade on a Check Point Firewall that enforces network access and audits data based on network location, the identity of the user, and the identity of the computer.  
Acronym: IDA.

**Identity Broker**

Identity Sharing mechanism between Identity Servers (PDP): (1) Communication channel between PDPs based on Web-API (2) Identity Sharing capabilities between PDPs - ability to add, remove, and update the identity session.

**Identity Collector**

Check Point dedicated client agent installed on Windows Servers in your network. Identity Collector collects information about identities and their associated IP addresses and sends it to the Check Point Firewalls for identity enforcement, you can download the Identity Collector package from the Support Center.

**Identity Collector Identity Sources**

Identity Sources for Check Point Identity Collector - Microsoft Active Directory Domain Controllers, Cisco `Vars_BladesFeatures.tp_cisco_ise_full` (`Vars_BladesFeatures.tp_cisco_ise`) Servers, or NetIQ eDirectory Servers.

**Identity Collector Query Pool**

A list of Identity Sources for Check Point Identity Collector.

**Identity Logging**

Software Blade on a Management Server to view Identity Logs from the managed Check Point Firewalls with enabled Identity Awareness Software Blade.

**Identity Server**

Check Point Firewall with enabled Identity Awareness Software Blade.

**Indicator**

Pattern of relevant observable malicious activity in an operational cyber domain, with relevant information on how to interpret it and how to handle it.

**Init**

State of a Cluster Member in the phase after the boot and until the Full Sync completes. A Cluster Member in this state does not process any traffic passing through cluster.

**Inline Layer**

Set of rules used in another rule in Security Policy.

**Intelligent Queuing Engine**

A bandwidth allocation algorithm that guarantees high priority traffic takes precedence over low priority traffic.

**Internal Network**

Computers and resources protected by the Firewall and accessed by authenticated users.

**IoC**

Indicator of Compromise. Artifact observed on a network or in an operating system that, with high confidence, indicates a computer intrusion. Typical IoCs are virus signatures and IP addresses, MD5 hashes of Malware files, or URLs or domain names of botnet command and control servers. Identified through a process of incident response and computer forensics, intrusion detection systems and anti-virus software can use IoC's to detect future attacks.

**IP Tracking**

Collecting and saving of Source IP addresses and Source MAC addresses from incoming IP packets during the probing. IP tracking is a useful for Cluster Members to determine whether the network connectivity of the Cluster Member is acceptable.

**IP Tracking Policy**

Internal setting that controls, which IP addresses should be tracked during IP tracking:  
(1) Only IP addresses from the subnet of cluster VIP, or from subnet of physical cluster interface (this is the default) (2) All IP addresses, also outside the cluster subnet.

**IPS**

Software Blade on a Check Point Firewall that inspects and analyzes packets and data for numerous types of risks (Intrusion Prevention System).

**IPsec VPN**

Software Blade on a Check Point Firewall that provides a Site to Site VPN and Remote Access VPN access.

**IRQ Affinity**

A state of binding an IRQ to one or more CPU cores.

**J**

---

**Jitter**

Variation in the delay of received packets. On the sending side, packets are spaced evenly apart and sent in a continuous stream. On the receiving side, the delay between each packet can vary according to network congestion, improper queuing or configuration errors.

**Jumbo Hotfix Accumulator**

Collection of hotfixes combined into a single package. Acronyms: JHA, JHF, JHFA.

**K**

---

**Kerberos**

An authentication server for Microsoft Windows Active Directory Federation Services (ADFS).

## L

---

### LLQ

Low Latency Queuing is a feature developed by Cisco to bring strict priority queuing (PQ) to class-based weighted fair queuing (CBWFQ). LLQ allows delay-sensitive data (such as voice) to be given preferential treatment over other traffic by letting the data to be dequeued and sent first.

### Load Sharing

A redundant cluster mode, where all Cluster Members process all incoming traffic in parallel. For more information, see "Load Sharing Multicast Mode" and "Load Sharing Unicast Mode". Synonyms: Active/Active, Load Balancing mode. Acronym: LS.

### Load Sharing Multicast

Load Sharing Cluster Mode, where all Cluster Members process all traffic in parallel. Each Cluster Member is assigned the equal load of  $[ 100\% / \text{number\_of\_members} ]$ . The Cluster Virtual IP address (that represents the cluster on that network) is associated with Multicast MAC Address 01:00:5E:X:Y:Z (which is generated based on last 3 bytes of cluster Virtual IP address on that network). A ClusterXL decision algorithm (Decision Function) on all Cluster Members decides, which Cluster Member should process the given packet.

### Load Sharing Unicast

Load Sharing Cluster Mode, where one Cluster Member (called Pivot) accepts all traffic. Then, the Pivot member decides to process this traffic, or to forward it to other non-Pivot Cluster Members. The traffic load is assigned to Cluster Members based on the hard-coded formula per the value of "Pivot\_overhead" attribute in the cluster object. The Cluster Virtual IP address (that represents the cluster on that network) is associated with: (1) Physical MAC Address of Pivot member (2) Virtual MAC Address.

### Log Server

Dedicated Check Point server that runs Check Point software to store and process logs.

### Logging & Status

Software Blade on a Management Server to view Security Logs from the managed Check Point Firewalls.

## M

---

### **Mail Transfer Agent**

Feature on a Check Point Firewall that intercepts SMTP traffic and forwards it to the applicable inspection component. Acronym: MTA.

### **Main Domain Management Server**

Domain Management Server on a Multi-Domain Security Management Server, on which you configured the object of your Traditional VSX Gateway or Traditional VSX Cluster. In this case, objects of your Virtual Systems are defined on different Domain Management Servers (Target Domain Management Servers).

### **Malware Database**

The Check Point database of commonly used signatures, URLs, and their related reputations, installed on a Check Point Firewall and used by the ThreatSpect engine.

### **Management High Availability**

Deployment and configuration mode of two Check Point Management Servers, in which they automatically synchronize the management databases with each other. In this mode, one Management Server is Active, and the other is Standby. Acronyms: Management HA, MGMT HA.

### **Management Interface**

(1) Interface on a Gaia Check Point Firewall or Cluster Member, through which Management Server connects to the Check Point Firewall or Cluster Member. (2) Interface on Gaia computer, through which users connect to Gaia Portal or CLI.

### **Management Server**

Check Point Single-Domain Security Management Server or a Multi-Domain Security Management Server.

### **Manual NAT Rules**

Manual configuration of NAT rules by the administrator of the Check Point Management Server.

### **Master**

State of a Cluster Member in a VRRP Cluster that processes all traffic in the cluster.

**Medium Path**

Packet flow on the Host Security Appliance, when the packet is handled by the SecureXL device. The CoreXL layer passes the packet to one of the CoreXL Firewall instances to process it. Even when CoreXL is disabled, the SecureXL uses the CoreXL infrastructure to send the packet to the single CoreXL Firewall instance that still functions. When the Medium Path is available, the SecureXL fully accelerates the TCP handshake. Rule Base match is achieved for the first packet through an existing connection acceleration template. The SecureXL also fully accelerates the TCP [SYN-ACK] and TCP [ACK] packets. However, once data starts to flow, to stream it for Content Inspection, an FWK instance now handles the packets. The SecureXL sends all packets that contain data to FWK for data extraction in order to build the data stream. Only the SecureXL handles the TCP [RST], TCP [FIN] and TCP [FIN-ACK] packets, because they do not contain data that needs to be streamed. The Medium Path is available only when CoreXL is enabled. Exceptions are: IPS (some protections); VPN (in some configurations); Application Control; Content Awareness; Anti-Virus; Anti-Bot; HTTPS Inspection; Proxy mode; Mobile Access; VoIP; Web Portals. Synonym: PXL.

**Mirror and Decrypt**

The Mirror and Decrypt feature on a Check Point Firewall that performs these actions: (1) Mirror only of all traffic - Clones all traffic (including HTTPS without decryption) that passes through, and sends it out of the designated physical interface. (2) Mirror and Decrypt of HTTPS traffic - Clones all HTTPS traffic that passes through, decrypts it, and sends it in clear-text out of the designated physical interface. Acronym: M&D.

**Mobile Access**

Software Blade on a Check Point Firewall that provides a Remote Access VPN access for managed and unmanaged clients. Acronym: MAB.

**Multi-Domain Log Server**

Dedicated Check Point server that runs Check Point software to store and process logs in a Multi-Domain Security Management environment. The Multi-Domain Log Server consists of Domain Log Servers that store and process logs from [[[Undefined variable tp\_cpfws]]] that are managed by the corresponding Domain Management Servers. Acronym: MDLS.

**Multi-Domain Security Management Server**

Dedicated Check Point server that runs Check Point software to host virtual Security Management Servers called Domain Management Servers. Synonym: Multi-Domain Security Management Server. Acronym: MDS.

**Multi-Queue**

Performance-enhancing technology on Check Point Firewall that configures more than one traffic queue for each network interface. Multi-Queue assigns more than one receive packet queue (RX Queue) and more than one transmit packet queue (TX Queue) to an interface. Multi-Queue is applicable only if SecureXL is enabled (this is the default).

Acronym: MQ.

**Multi-Version Cluster**

The Multi-Version Cluster mechanism lets you synchronize connections between Cluster Members that run different versions. This lets you upgrade to a newer version without a loss in connectivity and lets you test the new version on some of the Cluster Members before you decide to upgrade the rest of the Cluster Members. Acronym: MVC.

**N**

---

**NAC**

Network Access Control. This is an approach to computer security that attempts to unify endpoint security technology (such as Anti-Virus, Intrusion Prevention, and Vulnerability Assessment), user or system authentication and network security enforcement. Check Point's Network Access Control solution is called Identity Awareness Software Blade.

**Network Object**

Logical object that represents different parts of corporate topology - computers, IP addresses, traffic protocols, and so on. Administrators use these objects in Security Policies.

**Network Objective**

Defines how the cluster will configure and monitor an interface - Cluster, Sync, Cluster+Sync, Monitored Private, Non-Monitored Private. Configured in SmartConsole > cluster object > 'Topology' pane > 'Network Objective'.

**Network Policy Management**

Software Blade on a Management Server to manage an on-premises environment with an Access Control and Threat Prevention policies.

**Non-Blocking Mode**

Cluster operation mode, in which Cluster Member keeps forwarding all traffic.

**Non-Dedicated Management Interface**

Shared physical interface on Traditional VSX Gateway or Traditional VSX Cluster Members (supported only in versions R80.40 and lower), which carries user "production" traffic and through which Check Point Security Management Server or Multi-Domain Security Management Server connects to Traditional VSX Gateway or Traditional VSX Cluster Members. Non-DMI configuration requires the use of a Virtual Router or Virtual Switch. Acronym: Non-DMI.

**Non-Monitored Interface**

An interface on a Cluster Member, whose Network Type was set as Private in SmartConsole, in cluster object.

**Non-Pivot**

A Cluster Member in the Unicast Load Sharing cluster that receives all packets from the Pivot Cluster Member.

**Non-Sticky Connection**

A connection is called non-sticky, if the reply packet returns via a different Cluster Member, than the original packet (for example, if network administrator has configured asymmetric routing). In the Load Sharing mode, all Cluster Members are Active, and in Static NAT and encrypted connections, the Source and Destination IP addresses change. Therefore, Static NAT and encrypted connections through a Load Sharing cluster may be non-sticky.

**O**

---

**Observable**

Event or stateful property that can be observed in an operational cyber domain.

**Open Server**

Physical computer manufactured and distributed by a company, other than Check Point.

**P**

---

**Package Repository**

Collection of software packages that were uploaded to the Management Server. You can easily install these packages in SmartConsole on the managed Check Point Firewalls.

**Packet Selection**

Distinguishing between different kinds of packets coming from the network, and selecting, which member should handle a specific packet (Decision Function mechanism): CCP packet from another member of this cluster; CCP packet from another cluster or from a Cluster; Member with another version (usually older version of CCP); Packet is destined directly to this member; Packet is destined to another member of this cluster; Packet is intended to pass through this Cluster Member; ARP packets.

**PDP**

Check Point Firewall with Identity Awareness enabled that acts as Policy Decision Point: acquires identities from identity sources; shares identities with other gateways.

**PEP**

Check Point Firewall with Identity Awareness enabled that acts as Policy Enforcement Point: receives identities via identity sharing; redirects users to Captive Portal.

**Permission Profile**

Predefined group of SmartConsole access permissions assigned to Domains and administrators. With this feature you can configure complex permissions for many administrators with one definition.

**Pingable Host**

Some host (that is, some IP address) that Cluster Members can ping during probing mechanism. Pinging hosts in an interface's subnet is one of the health checks that ClusterXL mechanism performs. This pingable host will allow the Cluster Members to determine with more precision what has failed (which interface on which member). On Sync network, usually, there are no hosts. In such case, if switch supports this, an IP address should be assigned on the switch (for example, in the relevant VLAN). The IP address of such pingable host should be assigned per this formula:  $IP\_of\_pingable\_host = IP\_of\_physical\_interface\_on\_member + \sim 10$ . Assigning the IP address to pingable host that is higher than the IP addresses of physical interfaces on the Cluster Members will give some time to Cluster Members to perform the default health checks. Example: IP address of physical interface on a given subnet on Member\_A is 10.20.30.41; IP address of physical interface on a given subnet on Member\_B is 10.20.30.42; IP address of pingable host should be at least 10.20.30.5

**Pivot**

A Cluster Member in the Unicast Load Sharing cluster that receives all packets. Cluster Virtual IP addresses are associated with Physical MAC Addresses of this Cluster Member. This Pivot Cluster Member distributes the traffic between other Non-Pivot Cluster Members.

**Policy Layer**

Layer (set of rules) in a Security Policy.

**Policy Package**

Collection of different types of Security Policies, such as Access Control, Threat Prevention, QoS, and Desktop Security. After installation, Check Point Firewalls enforce all Policies in the Policy Package.

**Preconfigured Mode**

Cluster Mode, where cluster membership is enabled on all Cluster Members to be. However, no policy had been yet installed on any of the Cluster Members - none of them is actually configured to be primary, secondary, and so on. The cluster cannot function, if one Cluster Member fails. In this scenario, the "preconfigured mode" takes place. The preconfigured mode also comes into effect when no policy is yet installed, right after the Cluster Members came up after boot, or when running the 'cphaconf init' command.

**Predefined Report**

Default report included in a Check Point product that you can run right out of the box.

**Prevent**

UserCheck rule action that blocks traffic and files and can show a UserCheck message.

**Primary Multi-Domain Security Management Server**

The Multi-Domain Security Management Server in Management High Availability that you install as Primary.

**Primary Security Management Server**

The Security Management Server in Management High Availability that you install as Primary.

**Primary Up**

ClusterXL in High Availability mode that was configured as Switch to higher priority Cluster Member in the cluster object in SmartConsole: (1) Each Cluster Member is given a priority (in the cluster object). Cluster Member with the highest priority appears at the top of the table, and Cluster Member with the lowest priority appears at the bottom of the table. (2) The Cluster Member with the highest priority will assume the Active state. (3) If the current Active Cluster Member with the highest priority (for example, Member\_A), fails for some reason, or is rebooted, then failover occurs between Cluster Members. The Cluster Member with the next highest priority will be promoted to be Active (for example, Member\_B). (4) When the Cluster Member with the highest priority (Member\_A) recovers from a failure, or boots, then additional failover occurs between Cluster Members. The Cluster Member with the highest priority (Member\_A) will be promoted to Active state (and Member\_B will return to Standby state).

**Private Interface**

An interface on a Cluster Member, whose Network Type was set as 'Private' in SmartConsole in cluster object. This interface is not monitored by cluster, and failure on this interface will not cause any changes in Cluster Member's state.

**Probing**

If a Cluster Member fails to receive status for another member (does not receive CCP packets from that member) on a given segment, Cluster Member will probe that segment in an attempt to illicit a response. The purpose of such probes is to detect the nature of possible interface failures, and to determine which module has the problem. The outcome of this probe will determine what action is taken next (change the state of an interface, or of a Cluster Member).

**Provisioning**

Software Blade on a Management Server that manages large-scale deployments of Check Point Firewalls using configuration profiles. Synonyms: SmartProvisioning, SmartLSM, Large-Scale Management, LSM.

**PSL**

Passive Streaming Library. Packets may arrive at Check Point Firewall out of order, or may be legitimate retransmissions of packets that have not yet received an acknowledgment. In some cases, a retransmission may also be a deliberate attempt to evade IPS detection by sending the malicious payload in the retransmission. Check Point Firewall ensures that only valid packets are allowed to proceed to destinations. It does this with the Passive Streaming Library (PSL) technology. (1) The PSL is an infrastructure layer, which provides stream reassembly for TCP connections. (2) The Check Point Firewall makes sure that TCP data seen by the destination system is the same as seen by code above PSL. (3) The PSL handles packet reordering, congestion, and is responsible for various security aspects of the TCP layer, such as handling payload overlaps, some DoS attacks, and others. (4) The PSL is capable of receiving packets from the Firewall chain and from the SecureXL. (5) The PSL serves as a middleman between the various security applications and the network packets. It provides the applications with a coherent stream of data to work with, free of various network problems or attacks. (6) The PSL infrastructure is wrapped with well-defined APIs called the Unified Streaming APIs, which are used by the applications to register and access streamed data.

**PSLXL**

Technology name for combination of SecureXL and PSL (Passive Streaming Library) in versions R80.20 and higher. In versions R80.10 and lower, this technology was called PXL (PacketXL).

**Publisher PDP**

Check Point Firewall with Identity Awareness enabled that gets identities from an identity source/remote PDP and shares identities to a remote PDP. The Publisher PDP: (1) Initiates an HTTPS connection to the Subscriber PDP for each Identity to be shared (2) Verifies the CN and OU present in the subject field of the certificate presented (3) Verifies that the CA's certificate matches the certificate that was approved in advance by the administrator (4) Checks if the certificate presented is revoked (5) Shares identities including the information about user(s), machine(s) and Access Roles in the form of HTTP POST requests.

**Q**

---

**QoS**

Software Blade on a Check Point Firewall that provides policy-based traffic bandwidth management to prioritize business-critical traffic and guarantee bandwidth and control latency.

**QoS Action Properties**

Properties that define bandwidth allocation, limits, and guarantees for a security rule.

**R**

---

**RDED**

Retransmit Detect Early Drop. The bottleneck that results from the connection of a LAN to the WAN causes TCP to retransmit packets. RDED prevents inefficiencies by detecting retransmits in TCP streams and preventing the transmission of redundant packets when multiple copies of a packet are concurrently queued on the same flow.

**Ready**

State of a Cluster Member during after initialization and before promotion to the next required state - Active / Standby / VRRP Master / VRRP Backup (depending on the Cluster Mode). A Cluster Member in this state does not process any traffic passing through cluster. A member can be stuck in this state due to several reasons.

**Remote Access VPN**

An encrypted tunnel between remote access clients (such as Endpoint Security VPN) and a Check Point Firewall.

**Report**

Summary of network activity and Security Policy enforcement that is generated by Check Point products, such as SmartEvent.

**Route-Based VPN**

A routing method for participants in a VPN community, defined by network routes.

**Rule**

Set of traffic parameters and other conditions in a Rule Base (Security Policy) that cause specified actions to be taken for a communication session.

**Rule Base**

All rules configured in a given Security Policy. Synonym: Rulebase.

## S

---

### **Same VMAC**

Same Virtual MAC Address (see "VMAC"). When this feature is enabled in a ClusterXL (in the High Availability or Load Sharing Unicast mode), the Cluster Members use Virtual MAC (VMAC) addresses on the cluster interfaces instead of the real MAC addresses. Cluster interfaces that belong to the same subnet get the same VMAC address instead of their real MAC address. This feature helps avoid issues during the cluster operation, when switches block ports connected to the Cluster Members.

### **Secondary Multi-Domain Security Management Server**

The Multi-Domain Security Management Server in Management High Availability that you install as Secondary.

### **Secondary Security Management Server**

The Security Management Server in Management High Availability that you install as Secondary.

### **SecureXL**

Performance-enhancing technology on a Check Point Firewall that accelerates IPv4 and IPv6 traffic that passes through the Check Point Firewall.

### **Security Management Server**

Dedicated Check Point server that runs Check Point software to manage the objects and policies in a Check Point environment within a single management Domain. Synonym: Single-Domain Security Management Server.

### **Security Policy**

Collection of rules that control network traffic and enforce organization guidelines for data protection and access to resources with packet inspection.

**Selection**

The packet selection mechanism is one of the central and most important components in the ClusterXL product and State Synchronization infrastructure for 3rd-party clustering solutions. Its main purpose is to decide (to select) correctly what has to be done to the incoming and outgoing traffic on the Cluster Member. (1) In ClusterXL, the packet is selected by Cluster Member(s) depending on the cluster mode: In HA modes - by Active member; In LS Unicast mode - by Pivot member; In LS Multicast mode - by all members. Then the Cluster Member applies the Decision Function (and the Cluster Correction Layer). (2) In 3rd-party / OPSEC cluster, the 3rd-party software selects the packet, and Check Point software just inspects it (and performs State Synchronization).

**Service Account**

In Microsoft Active Directory, a user account created explicitly to provide a security context for services running on Microsoft Windows Server.

**SIC**

Secure Internal Communication. The Check Point proprietary mechanism with which Check Point computers that run Check Point software authenticate each other over SSL, for secure communication. This authentication is based on the certificates issued by the ICA on a Check Point Management Server.

**Silent Standby**

In the ClusterXL High Availability mode, this feature configures the Standby Cluster Member to communicate only through the Active Cluster Member. This feature is useful when it is necessary to connect from Standby Cluster Members to a host / server on the network.

**Site to Site VPN**

An encrypted tunnel between two or more Check Point Firewalls. Synonym: Site-to-Site VPN. Contractions: S2S VPN, S-to-S VPN.

**SmartConsole**

Check Point GUI application used to manage a Check Point environment - configure Security Policies, configure devices, monitor products and events, install updates, and so on.

**SmartDashboard**

Legacy Check Point GUI client used to create and manage the security settings in versions R77.30 and lower. In versions R80.X and higher is still used to configure specific legacy settings.

**SmartEvent Correlation Unit**

SmartEvent software component on a SmartEvent Server that analyzes logs and detects events.

**SmartEvent Server**

Dedicated Check Point server with the enabled SmartEvent Software Blade that hosts the events database.

**SmartProvisioning**

Software Blade on a Management Server (the actual name is "Provisioning") that manages large-scale deployments of Check Point Firewalls using configuration profiles. Synonyms: Large-Scale Management, SmartLSM, LSM.

**SmartUpdate**

Legacy Check Point GUI client used to manage licenses and contracts in a Check Point environment.

**Software Blade**

Specific security solution (module): (1) On a Check Point Firewall, each Software Blade inspects specific characteristics of the traffic (2) On a Management Server, each Software Blade enables different management capabilities.

**Standalone**

Configuration in which the Check Point Firewall and the Security Management Server products are installed and configured on the same server.

**Standby**

State of a Cluster Member that is ready to be promoted to Active state (if the current Active Cluster Member fails). Applies only to ClusterXL High Availability Mode.

**Standby Domain Server**

All Domain Management Servers for a Domain that are not designated as the Active Domain Management Server.

**Standby Security Management Server**

The Security Management Server in Management High Availability that is currently configured as Standby.

**State Synchronization**

Technology that synchronizes the relevant information about the current connections (stored in various kernel tables on Check Point Firewalls) among all Cluster Members over Synchronization Network. Due to State Synchronization, the current connections are not cut off during cluster failover.

**Sticky Connection**

A connection is called sticky, if all packets are handled by a single Cluster Member (in the High Availability mode, all packets reach the Active Cluster Member, so all connections are sticky).

**STIX**

Structured Threat Information eXpression™. A language that describes cyber threat information in a standardized and structured way.

**Subscriber PDP**

Check Point Firewall with Identity Awareness enabled that gets identities from a remote PDP. The Subscriber PDP: (1) Presents the configured SSL certificate to the Publisher PDP (2) Receives the information from the Publisher PDP after verifying the pre-shared secret in the POST requests.

**Subscribers**

User Space processes that are made aware of the current state of the ClusterXL state machine and other clustering configuration parameters. List of such subscribers can be obtained by running the 'cphaconf debug\_data' command.

**Sync Interface**

An interface on a Cluster Member, whose Network Type was set as Sync or Cluster+Sync in SmartConsole in cluster object. This interface is monitored by cluster, and failure on this interface will cause cluster failover. This interface is used for State Synchronization between Cluster Members. The use of more than one Sync Interfaces for redundancy is not supported because the CPU load will increase significantly due to duplicate tasks performed by all configured Synchronization Networks. Synonyms: Secured Interface, Trusted Interface.

**Synchronization Network**

A set of interfaces on Cluster Members that were configured as interfaces, over which State Synchronization information will be passed (as Delta Sync packets ). The use of more than one Synchronization Network for redundancy is not supported because the CPU load will increase significantly due to duplicate tasks performed by all configured Synchronization Networks. Synonyms: Sync Network, Secured Network, Trusted Network.

**System Counter**

SmartView Monitor data or report on status, activity, and resource usage of Check Point products.

**T**

---

**Target Domain Management Server**

Domain Management Server on a Multi-Domain Security Management Server, on which you configured the objects of your Virtual Systems. In this case, object of your Traditional VSX Gateway or Traditional VSX Cluster are defined on a different Domain Management Server (Main Domain Management Server).

**Terminal Servers Identity Agent**

Check Point dedicated client agent installed on Microsoft Windows-based application server that hosts Terminal Servers, Citrix XenApp, and Citrix XenDesktop services. This client agent acquires and reports identities to the Check Point Firewall with Identity Awareness enabled. In the past, this client agent was called Multi-User Host (MUH) Agent. You can download the Terminal Servers Identity Agent from Support Center.

**Threat Emulation**

Software Blade on a Check Point Firewall that monitors the behavior of files in a sandbox to determine whether or not they are malicious. Acronym: TE.

**Threat Emulation Private Cloud Appliance**

Check Point appliance that is certified to support the Threat Emulation Software Blade.

**Threat Extraction**

Software Blade on a Check Point Firewall that removes malicious content from files. Acronym: TEX.

**ThreatCloud**

The cyber intelligence center of all of Check Point products. Dynamically updated based on an innovative global network of threat sensors and invites organizations to share threat data and collaborate in the fight against modern malware.

**ThreatCloud Repository**

Cloud database with more than 250 million Command and Control (C&C) IP, URL, and DNS addresses and over 2,000 different botnet communication patterns, used by the ThreatSpect engine to classify bots and viruses. See:  
<https://www.checkpoint.com/infinity-vision/threatcloud/>

**ThreatSpect Engine**

Unique multi-tiered engine that analyzes network traffic and correlates data across multiple layers (reputation, signatures, suspicious mail outbreaks, behavior patterns) to detect bots and viruses.

**Traditional VSX Firewall**

Physical server that hosts Traditional VSX virtual networks, including all Virtual Devices that provide the functionality of physical network devices. It holds at least one Virtual System, which is called VS0.

**Transactions**

In the context of the Identity Collector, involves the aggregation of events from identity sources, the creation of a request, and the sending of this request to a target. The target then replies with a response. A transaction refers to this request-response.

**U**

---

**Updatable Object**

Network object that represents an external service, such as Microsoft 365, AWS, Geo locations, and more.

**URL Filtering**

Software Blade on a Check Point Firewall that allows granular control over which web sites can be accessed by a given group of users, computers or networks. Acronym: URLF.

**User Database**

Check Point internal database that contains all users defined and managed in SmartConsole.

**User Directory**

Software Blade on a Management Server that integrates LDAP and other external user Management Servers with Check Point products and security solutions.

**User Group**

Named group of users with related responsibilities.

**User Template**

Property set that defines a type of user on which a security policy will be enforced.

**UserCheck**

Functionality in a Check Point Firewall and endpoint clients that gives users a warning when there is a potential risk of data loss or security violation. This helps users to prevent security incidents and to learn about the organizational security policy.

**V**

---

**Virtual Device**

Logical object that emulates the functionality of a type of physical network object. Virtual Device can be on of these: Virtual Router, Virtual System, or Virtual Switch.

**Virtual Router**

Virtual Device on a Traditional VSX Gateway or Traditional VSX Cluster Member that functions as a physical router. Acronym: VR.

**Virtual Switch**

Virtual Device on a Traditional VSX Gateway or Traditional VSX Cluster Member that functions as a physical switch. Acronym: VSW.

**Virtual System**

Virtual Device on a Traditional VSX Gateway or Traditional VSX Cluster Member that implements the functionality of a Check Point Firewall. Acronym: VS.

**Virtual System Load Sharing**

Traditional VSX Cluster technology that assigns Virtual System traffic to different Active Cluster Members. Acronym: VSLS.

**VMAC**

Virtual MAC Address. When this feature is enabled in a ClusterXL (in the High Availability or Load Sharing Unicast mode), the current Active or Pivot Cluster Member sends Gratuitous ARP Requests (G-ARP) for its Cluster Virtual IP (VIP) addresses and Virtual MAC (VMAC) addresses in G-ARP updates. Cluster Members create a VMAC address for each Cluster VIP address. This feature helps avoid issues during a cluster failover, when switches do not integrate G-ARP updates into their ARP cache table.

**VPN Community**

A named collection of VPN domains, each protected by a VPN gateway.

**VPN Tunnel**

An encrypted connection between two hosts using standard protocols (such as L2TP) to encrypt traffic going in and decrypt it coming out, creating an encapsulated network through which data can be safely shared as though on a physical private line.

**VSX**

Virtual System Extension. Check Point virtual networking solution, hosted on a computer or cluster with virtual abstractions of Check Point Firewalls and other network devices. These Virtual Devices provide the same functionality as their physical counterparts.

**W**

---

**Warp Jump**

If two Virtual Systems connect to the same Virtual Switch or Virtual Router, then internally traffic that must pass from a network behind one Virtual System to a network behind another Virtual System, "jumps" from one Virtual System to another Virtual System without passing through the Virtual Switch or Virtual Router.

**Warp Link**

Logical interface that is created automatically: (1) In a VSNext topology, between a Virtual Gateway and a Virtual Switch (2) In a Traditional VSX topology, between a Virtual System and a Virtual Switch (3) In a Traditional VSX topology, between a Virtual System and a Virtual Router. Acronym: WRP.

**WFQ**

Weighted Fair Queuing. An algorithm to precisely control bandwidth allocation in QoS.

**WFRED**

Weighted Flow Random Early Drop. A mechanism for managing the packet buffers of QoS. Adjusting automatically and dynamically to the network traffic situation, WFRED remains transparent to the user.

**Z**

---

**Zero Phishing**

Software Blade on a Check Point Firewall (R81.20 and higher) that provides real-time phishing prevention based on URLs. Acronym: ZPH.
